Abstract

A series of 2',3'-dideoxy-2',2'-difluoro-4'-azanucleosides of both pyrimidine and purine nucleobases were synthesized in an efficient manner starting from commercially available L-pyroglutamic acid *via* glycosylation of difluorinated pyrrolidine derivative **15**. Several 4'-azanucleosides were prepared as a separable mixture of α - and β -anomers. The 6-chloropurine analogue was obtained as a mixture of N^7 and N^9 regioisomers and their structures were identified based on NOESY and HMBC spectral data. Among the 4'-azanucleosides tested as HIV-1 inhibitors in primary human lymphocytes, four compounds showed modest activity and the 5-fluorouracil analogue (**18d**) was found to be the most active compound ($EC_{50} = 36.9 \mu\text{M}$) in this series. None of the compounds synthesized in this study demonstrated anti-HCV activity.

Keywords

Azanucleosides; Synthesis; Anti-HIV-1; Anti-HCV; L-Pyroglutamic acid

1. Introduction

Considerable research efforts have been concentrated to prepare chemically modified nucleoside derivatives as effective anticancer¹ and antiviral agents.² Modifications in the carbohydrate moiety of nucleosides have resulted in improved biological properties.³ In this

regard, heteronucleosides, wherein the ring oxygen in the carbohydrate moiety is replaced by sulfur,⁴ nitrogen,⁵ and more recently selenium,⁶ have received much attention for their therapeutic applications. Among the bioactive thionucleosides, two examples are shown in Figure 1: thiarabine (4'-thioaracytosine, **1**) is currently in clinical trials as a potent antitumor agent⁷ and lamivudine (L-2',3'-dideoxy-3'-thiacytidine, **2**), in which the 4'-oxygen is present but a sulfur atom was placed at the 3'-position. Lamivudine was approved by the FDA in 1995 for the treatment of HIV infection.⁸ More recently, 4'-azanucleosides and 4'-selenonucleosides have shown significant anti-HCV⁹ and anticancer^{6a} activities, respectively. The synthesis of heterocyclic modified nucleosides has been recently reviewed.¹⁰ Another sugar modification that improves the biological properties of some nucleoside analogues is the introduction of fluorine,¹¹ a common functionality used in drug discovery efforts.¹²

The presence of fluorine in the carbohydrate moiety of nucleoside offers stabilization of the glycosidic bond. This increases the resistance to metabolic degradation while improving the lipophilicity to cross lipid membranes more effectively. Another important feature that arises from a structure activity relationship (SAR) analysis is the lack of a 3'-hydroxyl group in many of the nucleoside analogues that show anti-HIV activity. It is well known that the incorporation of 3'-deoxynucleosides in a viral DNA prevents chain elongation and terminates cell growth.¹³

Among fluorinated nucleosides with antiviral activity, representative examples are FddC (2',3'-dideoxy-2'-fluorocytosine, **3**)¹⁴ and FLT (3'-fluoro-3'-deoxythymidine, **4**)¹⁵ which inhibit the HIV reverse transcriptase. In addition, there are two nucleosides fluorinated at the 2'-position of the sugar moiety approved by the FDA for the treatment of cancer: (i) gemcitabine (2'-deoxy-2',2'-difluorocytidine, **5**), a potent drug against ovarian,¹⁶ pancreatic,¹⁷ and breast¹⁸ cancers, and (ii) clofarabine (2-chloro-2'-deoxy-2'-fluoroarabinoadenosine, **6**) which is used clinically for the treatment of leukemia in children.¹⁹

Although fluorine substitution in nucleosides and 4'-thionucleosides^{11a,20} has been extensively studied, few examples of fluorinated 4'-azanucleosides have been described and even less biological properties have been reported. Qiu and Qing²¹ carried out the preparation of pyrimidine 2'- and 3'-fluoromethyl-4'-azanucleosides, representing the only examples of fluorinated 4'-azanucleosides described to-date. To the best of our knowledge there are no other examples of 4'-azanucleosides in which the 2',2'-difluoro substituent is directly attached to the pyrrolidine moiety.

Consequently, studies on the synthesis and biological activity of these nucleoside derivatives are worth pursuing. On the basis of the above considerations and our ongoing interest in the preparation and biological evaluation of nucleoside analogues,²² herein, we report the synthesis and antiviral evaluation of a series of 2',3'-dideoxy-2',2'-difluoro-4'-azanucleosides.

2. Results and discussion

The synthesis of difluorinated pyrrolidine **15** as a substrate for the glycosylation reaction is outlined in Scheme 1. Commercially available L-pyroglutamic acid (**7**) possesses the correct configuration to furnish 4'-azanucleosides, which mimics the D-configuration of naturally occurring nucleosides. Conversion to L-pyroglutaminol (**8**) was accomplished in two steps via formation of the corresponding methylester from **7**, followed by reduction with NaBH₄.²³ Protection with 2,2-dimethoxypropane afforded the bicyclic lactam **9**. Electrophilic difluorination was achieved by the procedure described by Coward and

Konas.²⁴ Treatment of compound **9** with LDA followed by *N*-fluorodibenzenesulfonimide (NFSI) at -78 °C generated a 1.2:1.0 mixture of diastereomers, which was then subjected to the same reaction conditions again to furnish difluorinated product **10** in high overall yield. The acid hydrolysis of hemiaminal ether **10** with AcOH/MeCN/H₂O mixture afforded difluorinated L-pyroglytaminol (**11**) in 80% yield. Protection of the resulting hydroxyl group of **11** with TBDMSCl yielded the silylated compound **12**, which was then treated with Boc₂O under basic conditions to obtain the protected product **13** in high yield. Reduction of lactam **13** using LiBEt₃H in anhydrous THF provided **14** as a 1.9:1 mixture of anomers. Further reaction of **14** with Ac₂O gave **15** in quantitative yield, which was used for glycosylation reactions with silylated nucleobases.

2.1. Synthesis of pyrimidine 4'-azanucleosides

Glycosylation of **15** under Vorbrüggen's conditions²⁵ with various pyrimidine heterocyclic bases gave α/β mixtures of 4'-azanucleosides in high overall yields (78–85%). The ratio of α/β -anomers was determined by HPLC-MS of the crude reaction mixture (Scheme 2). The poor resolution of the ¹H NMR spectra for the TBDMS protecting 4'-azanucleosides hindered the determination of α/β -ratio. Thus, to assign the stereochemistry of the glycosylation products, TBDMS protecting group was removed and the configuration of the anomeric carbon was established by NOESY experiments showing the α -anomer as the major product. This was probably due to the steric hindrance of the bulky silyl protecting group. Similar results were also reported during glycosylation of a Boc-protected proline with pyrimidine base.²¹ Correlations between H1' and H4' as well as H5' and H6 were clearly observed in the β -anomers, while correlations between H4' and H6 of the corresponding nucleobase appeared in the α -anomers.

After glycosylation with silylated uracil, the resulting mixture of anomers **16a/17a** had different *R_f* values, and the products were easily separable by column chromatography. However the other nucleosides **16b-d/17b-d** were isolated as inseparable α/β -anomeric products. Removal of the TBDMS protecting group was accomplished under standard conditions by treating the separated pure anomers (**16a** and **17a**) or the anomeric mixtures **16b-c/17b-c** with TBAF in THF to afford 4'-azanucleosides **18/19** in excellent yields (Panel A, Scheme 3). It is noteworthy that after deblocking the TBDMS, the anomers **18d/19d** had different polarity and were separable by silica gel column chromatography (Panel B, Scheme 3). After the two step procedure of glycosylation–deprotection, four anomers were isolated as pure compounds (**18a**, **19a**, **18d** and **19d**) while **18b-c/19b-c** were isolated as non separable mixture of α/β -anomeric products.

Next, removal of the acetyl protecting group from the cytidine derivatives **18c/19c** was accomplished by treatment with ammonia affording an anomeric mixture of **20c/21c** (Scheme 4). The deprotection of Boc group from the uracil derivative **18a** was attempted with 2 equiv of TFA in CH₂Cl₂. However, only free uracil was isolated from the reaction mixture showing that despite the stabilization of the glycosidic bond by the two fluorine atoms, the unprotected 4'-azanucleosides are still prone to acid-mediated degradation. Additionally, it has been recently shown that the potent antiviral activity of a series of azanucleoside analogues was not compromised despite the presence of the Boc protecting group.⁹

2.2. Synthesis of purine 4'-azanucleosides

The success with the preparation of the pyrimidine nucleosides together with the few examples of purine 4'-azanucleosides described in the literature²⁶ encouraged us to try the coupling of **15** with purine nucleobases. It is well known that Vorbrüggen coupling²⁵ of silylated purine nucleobases typically results in *N*⁷/*N*⁹ isomeric mixtures. In addition, since

two anomers may result from each glycosylated regioisomer, four compounds may be present in the crude reaction mixture. As expected, after the coupling of **15** with silylated 6-chloropurine, the TLC of the crude reaction mixture showed the presence of four products. Mass spectrometry analysis indicated the same formula weight for all four products. Interestingly, for this particular case, four possible products had sufficient difference in the R_f values to be separated by silica gel column chromatography (Scheme 5).

To identify the structure of glycosylated products, it was necessary to remove the TBDMS protecting group (TBAF in THF). The structure of **26-29** was established by 2D NMR spectroscopy. NOESY experiments assisted in the assignment of the stereochemical configuration and HMBC experiments allowed us to determine the attachment of 6-chloropurine via N^7 or N^9 to the pyrrolidine moiety. In the case of nucleoside **26**, H2 and H8 of the 6-chloropurine moiety together with H1' showed correlation ($^3J_{CH}$) with C4 of the nucleobase (Figure 2). Correlation of these three hydrogen atoms with the same carbon can only be possible in the N^9 regioisomer. In the case of compound **28** the expected correlations for an N^7 isomer were observed, allowing confirmation of the structure. The same correlations patterns were also observed in the corresponding α -anomers. In addition, the structures were also confirmed by comparing the UV maxima with previously reported data (see experimental section).

The ratio of the four products obtained after glycosylation reaction, was determined by HPLC-MS data on the crude reaction mixture of protected nucleosides **22-25** (**22:23:24:25**, 8:27:12:53). As seen before for the pyrimidine nucleosides, the α -anomers were also the major products with the purine series. Interestingly, despite of higher reaction temperature (80 °C) employed during the glycosylation step, the N^7 product was dominant. This observation, which is unusual for glycosylation of 6-chloropurine base, is likely due to the sterically demanding structure of **15**.

The treatment of 6-chloropurine analogues **26-29** with ammonia furnished the corresponding adenine derivatives **30-33** (Scheme 6) in good yield.

3. Biological evaluation

3.1. Antiviral assays

All azanucleosides were tested against HIV-1_{LAI} using 3'-azido-3'-deoxythymidine (AZT, zidovudine) as a reference in an assay with human peripheral blood mononuclear (PBM) cells. We opted for including all products in the screen to maximize the database despite of the fact that some were isolated as mixture of anomeric products.

A summary of the data expressed as the effective concentration required to inhibit viral replication by 50% (EC_{50}) and 90% (EC_{90}) is shown in the Table 1. The 5-fluorouracil analogues **18d** ($EC_{50} = 36.9 \mu\text{M}$), **19d** ($EC_{50} = 44.5 \mu\text{M}$) together with the 6-chloro purine derivatives **27** ($EC_{50} = 64.5 \mu\text{M}$) and **29** ($EC_{50} = 92.3 \mu\text{M}$) showed modest activity when compared with the AZT as a control. It is noteworthy that the α -anomers demonstrated better activities in comparison to their β -counterparts. Also, it is of interest to observe modest activity despite the fact that all products were protected with the Boc group.

3.2. Cytotoxicity assays

All compounds were evaluated for their potential cytotoxicity in uninfected phytohemagglutinin stimulated human PBM cells, in lymphocytic CEM cells, and Vero (African green monkey Kidney) cells. The majority of compounds did not show any toxicity except the β -uracil analogue **19a** in Vero cells, **19a**, **18d**, **19d**, **27** and **29** in PBM cells, and **26**, **27** and **29** in CEM cells.

3.3. HCV Replicon assays²⁸

All compounds were tested at 10 μM in an HCV replicon assay using 2'-C-Me-Cytidine as the positive control. No anti-HCV activity was observed (data not shown).

4. Conclusions

In summary, we have developed an efficient synthesis of novel 2',3'-dideoxy-2',2'-difluoro-4'-azanucleosides both as pyrimidine and purine analogues. A high yielding sequence of electrophilic difluorination of L-pyrroglutamic acid followed by the coupling of protected pyrrolidine **15** as the glycosyl donor with four pyrimidine and one purine nucleobase was established. The pyrimidine 4'-azanucleosides were obtained as mixtures of α - and β -anomeric products, increasing the breadth of novel nucleoside analogues available for biological screening. The α -anomers were obtained as major products during glycosylation. After glycosylation and TBDMS deprotection, the anomeric mixtures of U (**18a/19a**) and 5-F-U (**18d/19d**) analogues could be easily separated by silica gel column chromatography. However, the anomeric mixtures of T (**18b/19b**) and C (**18c/19c**) analogues could not be separated by silica chromatography. Gratifyingly, glycosylation with 6-chloropurine afforded a separable mixture of four nucleosides arising from the formation of N^7/N^9 glycosylated regioisomers and the corresponding α/β -anomers. These isomers were characterized based on 2D NMR spectroscopy, and constitute the only examples of fluorinated purine 4'-azanucleosides described to date. Further reaction with ammonia of each isomer furnished a direct route for the purine nucleosides **30-33**. All fluorinated 4'-azanucleosides synthesized were tested as inhibitors of HIV-1 in PBM cells. The α -5-F-U analogue **18d** was found to be the most active compound ($\text{EC}_{50} = 36.9 \mu\text{M}$) in this series. These compounds did not exhibit anti-HCV activity in a hepatitis C replicon assay probably due to the lack of a 3'-hydroxyl group or mimic for the moiety. The limited examples of fluorinated 4'-azanucleosides described in the literature and the interesting activity found in some of the nucleosides described in this work, warrants further studies with this new class of compounds.

5. Experimental section

All reagents were bought from Aldrich and Acros at highest commercial quality and used without further purification. All non-aqueous reactions were carried out under anhydrous conditions in dry, freshly distilled solvents. THF and CH_2Cl_2 were purified by passage through a bed of activated alumina. Reactions were monitored by TLC carried out on 0.25 mm E. Merck silica gel plates (60F-254) using UV light as visualizing agent and/or acidic aqueous permanganate. Flash chromatography was performed using silica gel 60 (230–400 mesh). LC-ESI-MS analyses were carried out in a chromatogram with UV detector at 254 nm using Agilent Poroshell column 120 SB, C18, or Mediterranean column (250 \times 45 mm) flow 1 mL min^{-1} r.t. gradient MeCN- H_2O as eluent. Melting points were taken on samples in open capillary tubes and are uncorrected. ^1H , ^{13}C NMR, and DEPT were obtained using Varian Mercury and/or Bruker 300.13, 400.13 or 600.13 MHz for ^1H , and 75.5, 100.61 MHz or 150.92 for ^{13}C . The same spectrometers were used for the acquisition of ^1H - ^1H homonuclear (COSY and NOESY) and ^1H - ^{13}C heteronuclear (HSQC and HMBC) correlations. Optical rotations were recorded on a Jasco P-1010 polarimeter and values are reported as follows: $[\alpha]_{\lambda}^T$ (c: g/100 mL, solvent). High resolution mass spectra (HRMS) were recorded on a VG 7070 HS mass spectrometer under electron spray ionization (ESI) conditions. The *tert*-butyldimethyl silyl protecting group is abbreviated below as TBDMS.

Synthesis of (S)-Pyroglutaminol (8)

To a cooled solution of L-pyroglutamic acid (**7**) (6.0 g, 41.9 mmol) in dry MeOH (80 mL), was added SOCl₂ (4.9 g, 41.9 mmol) dropwise with magnetic stirring at room temperature for 2 h. The mixture was concentrated under vacuum to give the methyl ester as clear oil (5.2 g, 80%). This oil (33.2 mmol) was poured in a flask, dissolved in dry EtOH (80 mL) and NaBH₄ (2.54 g, 67.0 mmol) was added portionwise. After stirring at room temperature for 2 h, the mixture was acidified with concentrated HCl to pH 1. Solvents were removed under vacuum and the residue subjected to flash chromatography (15% MeOH, CH₂Cl₂) to afford **8** (3.3 g 28.5 mmol). The synthesis of **8** has been previously described.²³

Synthesis of (5S)-2,2-dimethyl-8-oxo-1-aza-3-oxa-bicyclo[3.3.0]octane (9)

A mixture of compound **8** (3.3 g, 28.7 mmol), CSA (0.68 mmol, 158 mg) and 2,2-dimethoxypropane (DMP; 12 mL) was refluxed for 2 h. The volatiles components (DMP, MeOH) were removed in vacuo. Fresh DMP was added, and the mixture again refluxed for 2 h. This process was repeated a total of three times. After the final evaporation the residue was subjected to flash chromatography (50% AcOEt/hexane) and then distilled under vacuo to afford **9** as a colorless oil (3.67 g, 83%). The synthesis of **9** has been previously described.²⁴

Synthesis of (5S)-2,2-dimethyl-7,7-difluoro-8-oxo-1-aza-3-oxa-bicyclo[3.3.0]octane (10)

Diisopropyl amine (2.3 mL, 16.5 mmol) was added to dry THF with magnetic stirring and the solution was cooled to -78 °C. *N*-butyllithium (3.7 mL, 13.9 mmol) was added slowly and the mixture was stirred for 1 h. A solution of **9** (1.8 g, 11.6 mmol) in THF (9 mL) was added slowly. The mixture was stirred for 1 h at -78 °C before the addition of a solution of *N*-fluorodibenzenesulfonimide (NFSI; 5.19 g, 16.5 mmol) in THF (18 mL), the solution was again stirred for 45 min and then quenched by the addition of saturated NH₄Cl. THF was removed under vacuo and the residue extracted with AcOEt and water. The combined organic layers were dried over Na₂SO₄, filtered and evaporated. The residue was purified by flash chromatography (20–50% AcOEt-hexane) to give the monofluorinated lactam (1.84 g, 92%). The same fluorination procedure was carried out using the previous monofluorinated lactam (1.84 g, 10.6 mmol) as a substrate to get the difluorinated compound **10** (1.72 g, 85%) as a pale yellow oil. The synthesis of **10** has been previously described.²⁴

Synthesis of (5S)-3,3-difluoro-5-hydroxymethyl-2-pyrrolidinone (11)

Compound **10** (1.65 g, 8.37 mmol) was stirred in a mixture of acetic acid, acetonitrile and water (14:3:3, v/v) (20 mL). The solution was heated at 90 °C for 14 h. After evaporation of solvents, the residue was purified by flash chromatography (10% MeOH/CH₂Cl₂) to yield pure **11** as a white solid (1.04 g, 80%). The synthesis of **11** has been previously described.²⁴

Synthesis of (5S)-5-(*tert*-butyldimethylsilyloxymethyl)-3,3-difluoro-2-pyrrolidinone (12)

To a solution of **11** (960 mg, 6.39 mmol) in dry CH₂Cl₂ (40 mL) at 0 °C was added imidazole (566 mg, 8.31 mmol), DMAP (0.63 mmol, 78 mg) and TBDMSCl (1.25 g, 8.31 mmol). The reaction was stirred at room temperature for 30 min, quenched by the addition of water (300 μL) and extracted with CH₂Cl₂. The combined organic layers were dried over Na₂SO₄, solvents were evaporated and the residue subjected to flash chromatography (15% AcOEt/hexane) to afford **12** (1.8 g, 87%) as viscous oil. R_f: (20% AcOEt/hexane):0.23. [α]_D²⁰ = +35 (c 0.5, CH₂Cl₂). ¹H NMR (CDCl₃, 400.13 MHz): δ 0.05 (s, 6H, Me₂Si), 0.87 (s, 9H, ^tBu), 2.29 (m, 1H, H3), 2.55 (m, 1H, H-3), 3.54 (dd, 1H, CH₂O, *J*_{HH} 6.2 Hz, *J*_{HH} 10.3 Hz), 3.67 (dd, 1H, CH₂O, *J*_{HH} 4.4 Hz, *J*_{HH} 10.4 Hz), 3.80 (m, 1H, H-5), 7.67 (br s, 1H, NH). ¹³C NMR (CDCl₃, 100.61 MHz): δ 5.4 (2CH₃, ^tBu), 18.4 (1C, ^tBu), 26.0 (3CH₃, ^tBu), 33.1 (t, C-4, *J*_{CF} 22.1 Hz), 50.7 (C-5), 65.1 (CH₂O), 118.0 (t, C-3, *J*_{CF} 249.5 Hz), 166.7 (t,

C=O, J_{CF} 31.2 Hz). HRMS (ESI⁺) calcd for C₁₁H₂₁F₂NO₂SiNa [M+Na]⁺ 288.1202, found 288.1203.

Synthesis of (5S)-5-(*tert*-butyldimethylsilyloxymethyl)-*N*-*tert*-butyloxycarbonyl-3,3-difluoro-2-pyrrolidinone (**13**)

To a solution of **12** (854 mg, 3.21 mmol), in dry CH₂Cl₂ (28 mL), was added Et₃N, (0.6 mL, 4.17 mmol), DMAP (427 mg, 3.53 mmol) and Boc₂O (1.41, 6.42 mmol). The reaction was stirred at room temperature for 30 min. Solvents were concentrated to dryness and the residue purified by column chromatography (10% AcOEt/hexane) to give **13** (1.13 g, 96%). R_f (20% AcOEt/hexane): 0.53. [α]_D²⁰ = -51 (c 0.5, CH₂Cl₂). ¹H NMR (CDCl₃, 400.13 MHz): δ 0.02 (s, 6H, Me₂Si), 0.85 (s, 9H, ^tBu), 1.53 (s, 9H, ^tBu), 2.48 (m, 2H, H-4), 3.70 (dd, 1H, CH₂O, J_{HH} 2.5 Hz, J_{HH} 10.3 Hz), 3.83 (dd, 1H, CH₂O, J_{HH} 5.1 Hz, J_{HH} 10.3 Hz), 4.22 (m, 1H, H-5). ¹³C NMR (CDCl₃, 100.61 MHz): δ 5.7 (^tBu), 18.4 (^tBu), 26.0 + 27.8 (^tBu + Boc), 31.0 (t, C-4, J_{CF} 22.1 Hz), 53.4 (C-5), 62.3 (CH₂O), 84.7 (Boc), 116.6 (t, C-3, J_{CF} 251.0 Hz), 149.2 (C=O), 166.7 (t, C=O, J_{CF} 32.2 Hz). MS (ESI⁺, m/z) 382 [(M+NH₄)⁺ 100%]; 388 [(M+Na)⁺ 10%]. HRMS (ESI⁺) calcd for C₁₆H₂₉F₂NO₄SiNa [M+Na]⁺ 388.1726, found 388.1727.

Synthesis of (5S)-5-(*tert*-butyldimethylsilyloxymethyl)-*N*-*tert*-butyloxycarbonyl-3,3-difluoro-2-hydroxy-pyrrolidine (**14**) (mixture of anomers)

To a solution of **13** (368 mg, 1.0 mmol) in anhydrous THF (9.3 mL) was slowly added dropwise LiEt₃BH (504 μL, 0.5 mmol) at -78 °C under argon atmosphere. The reaction mixture was stirred 1 h, then additional LiEt₃BH (706 μL, 0.70 mmol) was added. After 1 h, the reaction was quenched with water (4 mL) and the organic solvent was evaporated. The aqueous phase was extracted with CH₂Cl₂ dried over Na₂SO₄, filtered and concentrated under vacuum. The resulting residue was purified by flash chromatography (30% AcOEt/hexane) to afford a inseparable mixture of anomers **14** (311 mg, 84%) in 4:1 ratio. R_f (20% AcOEt/hexane): 0.51. Major isomer ¹H NMR (CDCl₃, 400.13 MHz): δ 0.11 (s, 6H, Me₂Si), 0.91 (9H, ^tBu), 1.48 (s, 9H, Boc), 2.45 (m, 2H), 3.39 (d, 1H, CH₂O, J_{HH} 10.2 Hz), 3.83 (d, 1H, CH₂O, J_{HH} 10.0 Hz), 4.07 (d, 1H, H-5, J_{HH} 10.0 Hz), 5.16 (t, 1H, H-2, J_{HF} 10.2 Hz). Minor isomer ¹H NMR (CDCl₃, 400.13 MHz): δ 0.11 (s, 6H, ^tBu), 0.91 (9H, ^tBu), 1.48 (s, 9H, Boc), 2.45 (m, 2H), 3.51 (d, 1H, CH₂O, J_{HH} 9.8 Hz), 3.69 (m, 1H, CH₂O), 4.21 (m, 1H, H-5), 5.16 (m, 1H, H-2). MS (ESI⁺, m/z) 368 [(M+H)⁺ 10%]; 390 [(M+Na)⁺ 100%]. HRMS (ESI⁺) calcd for C₁₆H₃₁F₂NO₄SiNa [M+Na]⁺ 390.1883, found 388.1885.

Synthesis of (5S)-2-acetyloxy-5-(*tert*-butyldimethylsilyloxymethyl)-*N*-*tert*-butyloxycarbonyl-3,3-difluoro-pyrrolidine (**15**) (mixture of anomers)

To a solution of anomers **14** (300 mg) in CH₂Cl₂ (10 mL) was added Et₃N (3.4 mL, 2.5 mmol), Ac₂O (1.2 mL, 12.0 mmol), and DMAP (catalytic). The solution was allowed to stir for 30 min. Solvents were evaporated and the residue purified by flash column chromatography (20% AcOEt/hexane) to afford **15** (332 mg, 100%). The presence of TBDMS protecting complicates the analysis of the NMR spectra. R_f (20% AcOEt/hexane): 0.64. ¹H NMR (CDCl₃, 400.13 MHz): δ 0.11 (s, 6H, Me₂Si), 0.95 (9H, ^tBu), 1.47 (s, 9H, Boc), 2.09 (m, 2H), 3.77 (br s, 1H), 4.01 (br s, 2H), 6.49 (br s, 1H). MS (ESI⁺, m/z) 409 [(M+H)⁺ 10%]; 432 [(M+Na)⁺ 100%]. HRMS (ESI⁺) calcd for C₁₈H₃₃F₂NO₅SiNa [M+Na]⁺ 432.1988, found 432.2003.

General procedure for glycosylation of fluorinated pyrrolidine **15** with pyrimidine bases followed by deprotection. Synthesis of nucleosides **18a-d/19a-d**

To a stirred solution of **15** (0.3 mmol, 122 mg) and the different bases (1.2 mmol) in dry MeCN was added BSA (0.59 mL, 1.8 mmol). The reaction mixture was stirred at 80 °C for

1 h. This solution was cooled to 0 °C and TMSOTf (0.17 mL, 0.83 mmol) was added dropwise. The solution was heated at 80 °C for 1 h. The reaction was quenched by the addition of Et₃N (0.2 mL). Solvents were evaporated and the resulting residue purified by column chromatography (20–50% AcOEt/hexane) to afford the protected 4'-azanucleosides (**16a-d/17a-d**) (78–85%). Then stirred solutions of the nucleoside derivatives in THF (4 mL) were treated with 1.0 M solutions of TBAF in THF (1.5 equiv). Reactions were quenched with water, and after evaporation of solvents the residues purified by flash chromatography (2–5% MeOH/CH₂Cl₂) to afford the pure 4'-azanucleosides (**18a-d/19a-d**) as white solids (90–99%).

1-[(2S,5S)-N-tert-Butyloxycarbonyl-3,3-difluoro-5-(hydroxymethyl)pyrrolidin-2-yl]-uracil (18a)

61% yield after glycosylation and 99% yield for TBDMS deprotection. R_f (5% MeOH/CH₂Cl₂): 0.19. mp: 82–85 °C. Acknowledgments

Financial support of this work by the Spanish Ministerio de Educación y Ciencia (MEC) (Project MEC-CTQ-2007-61126) and PCTI (2006–2009)/FEDER (2007–2013) Asturias (Project EQUIP09-07) are gratefully acknowledged. S.M.-M. thanks MEC for a predoctoral fellowship. We also acknowledge the National Institutes of Health (NIH) for financial support of this work through Grant Number R01 GM081484. We thank the National Science Foundation for instrumentation grants CHE9709183 and CHE0741968. We also thank Dr. Y. Su (UCSD Mass Spectrometry) for mass analysis. This work was also supported in part by NIH grant 2P30-AI-050409 and the Department of Veterans Affairs.

Selected structures of bioactive nucleosides.

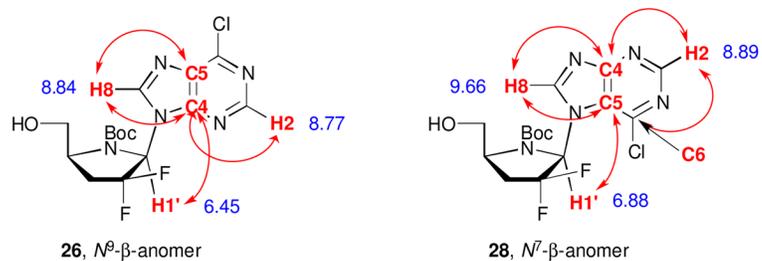

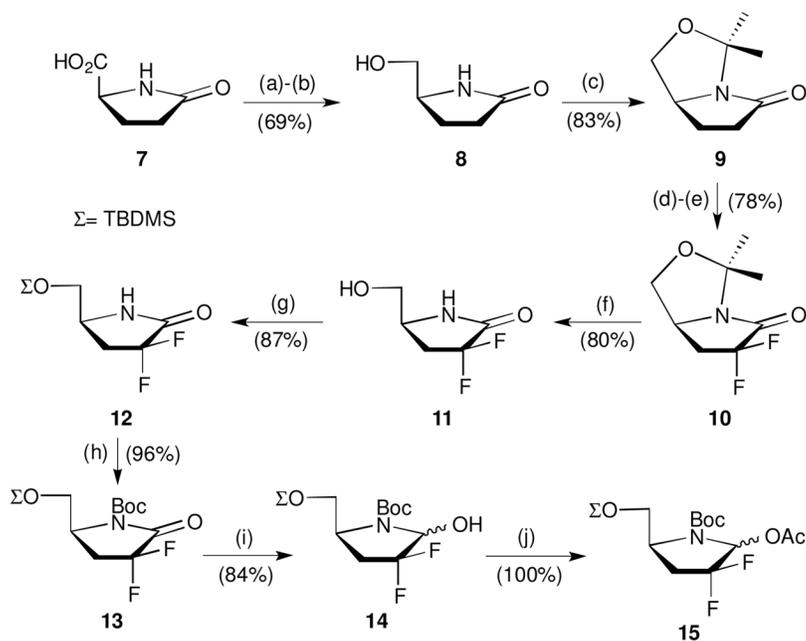

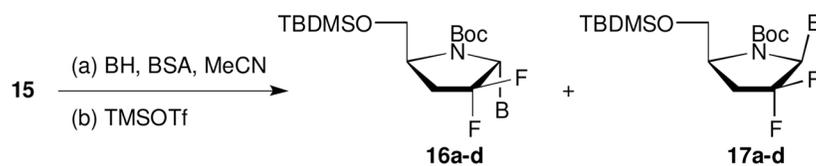

Figure 2. HMBC correlations of N^6 and N^7 regioisomers. In red are correlations mentioned in the text. The ^1H NMR values (δ ppm) are in blue.

**Scheme 1.**

Synthesis of **15**. *Reagents and conditions:* (a) 1 equiv SOCl_2 , MeOH, r.t., 4 h; (b) 2 equiv NaBH_4 , EtOH, r.t., 14 h; (c) 2,2-dimethoxypropane (solvent), 0.03 equiv CSA, reflux, 2 h; (d) 1.4 equiv tPr_2NH , 1.2 equiv $n\text{BuLi}$, 1.4 equiv NFSI, THF, -78°C ; (e) 1.4 equiv tPr_2NH , 1.2 equiv $n\text{BuLi}$, 1.4 equiv NFSI, THF, -78°C ; (f) AcOH/MeCN/ H_2O (14:3:3), 90°C , 14 h; (g) 1.3 equiv TBDMSCl, 1.3 equiv imidazole, 0.1 equiv DMAP, CH_2Cl_2 , r.t., 30 min; (h) 2 equiv Boc_2O , 1.3 equiv Et_3N , 1.1 equiv DMAP, CH_2Cl_2 , r.t., 30 min; (i) 1.2 equiv LiEt_3BH , THF, -78°C , 1 h; (j) 15 equiv Ac_2O , 30 equiv Et_3N , CH_2Cl_2 , r.t., 30 min.

	Yield (%) ^a	Ratio (α : β)
16a+17a , B= U	85	2.3:1
16b+17b , B= T	78	2.0:1 ^b
16c+17c , B= C ^{Ac}	82	2.0:1
16d+17d , B= 5FU	83	2.7:1

^aYield of the glycosylation mixture (**16+17**)

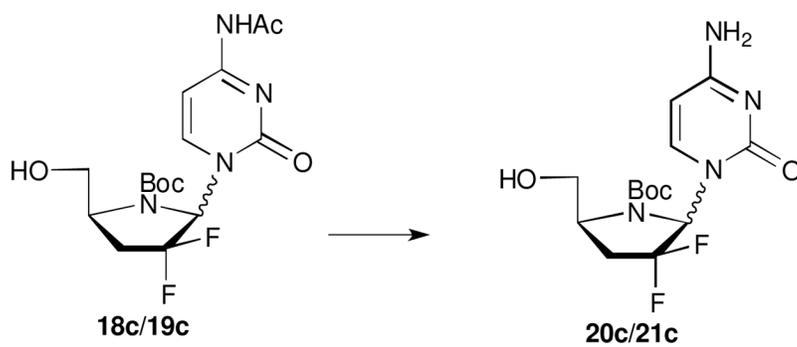

^bRatio calculated by HPLC after TBDMS deprotection

Scheme 2.

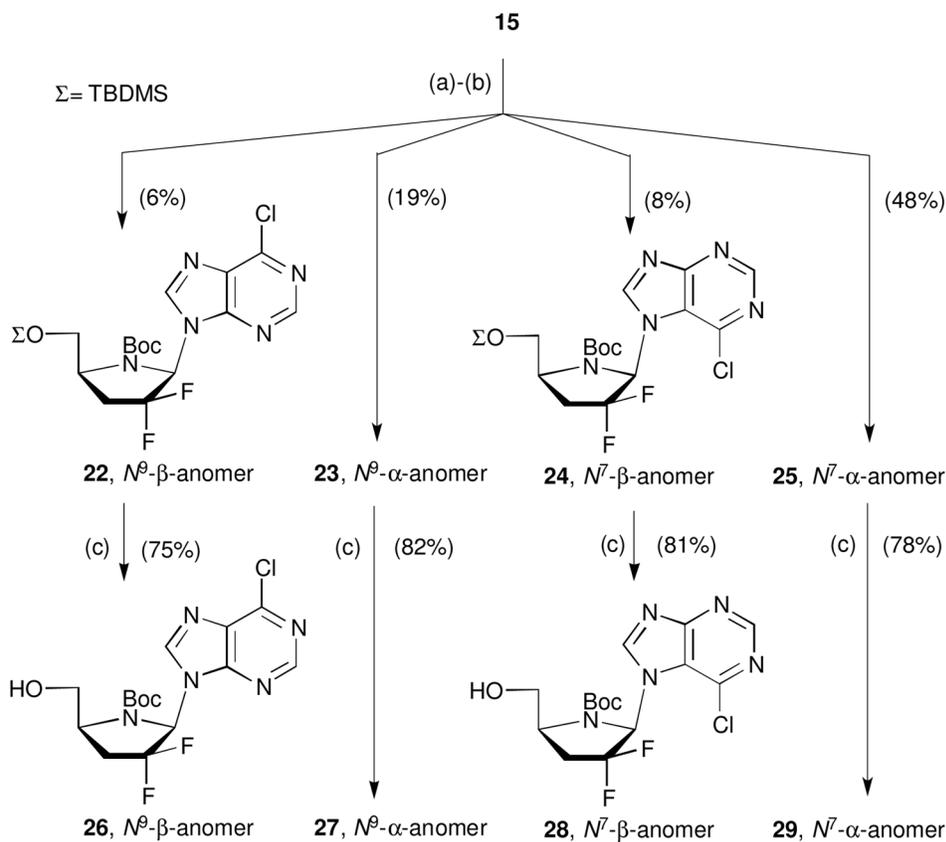

Glycosylation of **15** with pyrimidines. *Reagents and conditions:* (a) 1 equiv **15**, 4 equiv base (BH= uracil, thymine, *N*⁴-acetylcytosine, and 5-fluorouracil), 6 equiv BSA, MeCN, 80 °C, 1 h; (b) 2.7 equiv TMSOTf, 0–80 °C, 30 min, 78–85% over two steps.

**Scheme 3.**

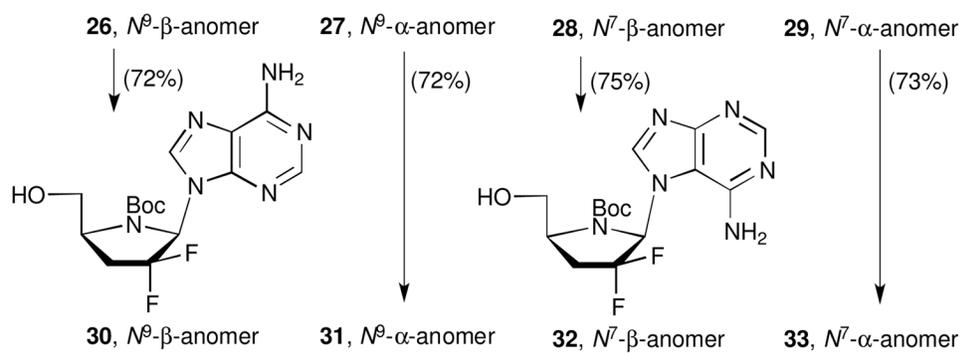

Removal of TBDMS protecting group. *Reagents and conditions:* 1.5 equiv TBAF, THF, 0–25 °C, 1 h.

**Scheme 4.**

Synthesis of **20c/21c**. *Reagents and conditions:* NH_3 sat-MeOH, r.t., 1 h, 82%.

**Scheme 5.**

Glycosylation of **15** with 6-chloropurine. *Reagents and conditions:* (a) 1 equiv **15**, 4 equiv 6-chloropurine, 6 equiv BSA, MeCN, 80 °C, 1 h; (b) 2.7 equiv TMSOTf, 0–80 °C, 30 min; (c) 1.5 equiv TBAF, THF, r.t., 1 h.

**Scheme 6.**

Synthesis of adenine 4'-azanucleosides **30-33**. *Reagents and conditions:* NH_3 sat-MeOH, 100 °C, 3 h.

Table 1

Effect of analogues against HIV-1_{LA1} in human peripheral blood mononuclear (PBMC) cells

Analogue	Base	Anti-HIV-1 activity in PBMC cells ^a			Cytotoxicity (IC ₅₀ , μM) ^b		
		EC ₅₀ , μM	EC ₉₀ , μM	PBM cells	CEM cells	VERO cells
