### Abstract

Serratezomine A is a member of the structurally diverse class of compounds known as the *Lycopodium* alkaloids. The key supporting studies and successful total synthesis of serratezomine A are described in this account. Significant features of the synthesis include the first application of free radical mediated vinyl amination and Hwu's oxidative allylation in a total synthesis, and an intramolecular lactonization via a transannular  $S_Ni$  reaction. Minimal use of protecting groups and the highly diastereoselective formation of a hindered, quaternary stereocenter using an umpolung allylation are also highlights from a strategy perspective. Observation of quaternary carbon epimerization via a *retro*-Mannich/Mannich sequence highlights the additional challenge presented by the axial alcohol at C8 in serratezomine A.

### INTRODUCTION

Serratezomine A (**1**), a  $C_{16}N$  alkaloid belonging to the fawcettimine class of *Lycopodium* alkaloids,<sup>1,2</sup> was isolated from the club moss *L. serratum* var. *serratum* in 2000 (Figure 1).<sup>3</sup> Serratezomine A exhibited moderate cytotoxicity against murine lymphoma L1210 cells ( $IC_{50} = 9.7 \mu\text{g/mL}$ ) and human epidermoid carcinoma KB cells ( $IC_{50} > 10 \mu\text{g/mL}$ ) and demonstrated strong anticholinesterase activity. Of the *Lycopodium* alkaloids, huperzine A (**2**, Figure 1), a constituent alkaloid, has shown the most promising biological activity. It has been used for the treatment of neurodegenerative disorders relating to the neurotransmitter acetylcholine, including myasthenia gravis and Alzheimer's disease<sup>4,5,6</sup> and is available as a dietary supplement to enhance memory.

Supporting Information

Includes  $^1\text{H}$  and  $^{13}\text{C}$  NMR spectra of all new compounds not previously reported including the title compound (**1**), **S1** (precursor to **19**), and **S2** (formed along with **42**), along with X-ray data for **31** (co-crystallized with **S4**), **42**, and **51**, and select 2D data used for structural assignments. This material is available free of charge via the Internet at <http://pubs.acs.org>.

The complex framework of the *Lycopodium* alkaloids makes them challenging, yet attractive targets for total synthesis. Serratezomine A contains six contiguous stereocenters including a spirocyclic all-carbon center contained within a tetracyclic ring system. The structure of **1** was determined by  $^1\text{H}$  and  $^{13}\text{C}$  NMR, a combination of 2D NMR techniques, and from data obtained by the structurally similar serratinine (**3**).<sup>3</sup> In addition, serratinine (**3**) was converted to **1** via a biomimetic, one-pot modified Polonovski rearrangement.<sup>7</sup> The first total synthesis of **1** was recently completed by us,<sup>8</sup> and elegant syntheses of the structurally similar serratinine (**3**)<sup>9,10</sup> and fawcettimine (**4**)<sup>11</sup> have also been accomplished. Still other *Lycopodium* alkaloids have been the subject of recent publications.<sup>12</sup> In this report, our complete study leading to the successful preparation of (+)-serratezomine A through total chemical synthesis is described. The steric influence of the axial alcohol was evident in the discovery of an undesired epimerization at the spirocyclic carbon, which was successfully overcome in the final synthetic route.

Our retrosynthetic approach to serratezomine A (**1**) is presented in Scheme 1. The first two disconnects involve the piperidine and lactone rings. The piperidine ring formation is evident after functionalization of the pendant alkene in **5** to provide a leaving group for imine cyclization and reduction to the bicyclic amine. The lactone ring is formed after saponification of the ester and displacement of the mesylate. Target **5** provides an intermediate that contains all of the carbons in the natural product. Installation of the allyl group was to be attempted through a diastereoselective allylation of vinylogous amide **6**. The cyclohexanone ring in **6** was anticipated to result from an intramolecular Michael addition of the vinylogous amide and  $\alpha,\beta$ -unsaturated ester in **7d**. Selectivity in this step was projected to be the result of  $A^{1,3}$ -strain minimization<sup>13</sup> and favor an axial ethyl acetate substituent as depicted in **7d**. The *N*-protected vinylogous amide represents the convergent point in our synthesis. It was expected to be accessible via acylation of  $\beta$ -stannylenamine **9d** with acid chloride **8**. The  $\beta$ -stannylenamine was synthesized by methodology developed earlier by us, involving a non-conventional radical-mediated 5-*exo*-trig cyclization of an imine.<sup>14,15</sup> The required imine (**11d**) is accessible in three steps from the commercially available chloride **12** by a Gabriel amine synthesis. The acid chloride portion (**8**) was anticipated to be accessible from  $\alpha,\beta$ -unsaturated aldehyde **10** using a Brown crotylation. The two stereocenters in **8** would be used to direct the formation of all remaining stereocenters in **1**.

## RESULTS AND DISCUSSION

The synthesis began with selective ozonolysis of the terminal alkene in commercially available ethyl sorbate (**13**, Scheme 2).<sup>16</sup> The  $\alpha,\beta$ -unsaturated aldehyde (**10**) was isolated after vacuum distillation in up to 93% yield.<sup>17</sup> Next, the homoallylic alcohol was installed in the *anti*-configuration using a Brown crotylation. This reaction is especially difficult with unsaturated aldehydes and tends to provide lower yields and selectivities.<sup>18</sup> Fortunately, using a modification on multigram scale that included a large dry ice bath that could be maintained for an extended period, the desired product was formed with good enantioselectivity and yield (**14**, 93% ee, 79% yield). Careful temperature control was imperative to good stereoselection since considerable conversion could occur as the reaction mixture warmed during the quenching process. The structure of the main diastereomer was confirmed by formation of both (*R*)- and (*S*)-Mosher esters in which NMR analysis led to the determination of relative stereochemistry as depicted for alcohol **14**.<sup>19</sup> The majority of the terpene alcohol (**15**, a byproduct from the chiral auxiliary oxidation) could be fractionally distilled and the crude reaction mixture containing the two alcohols (**14** and any remaining **15**) was subjected to TBS protection to afford the mixture of TBS ethers. The TBS group provided greater separation of the two products by column chromatography and allowed for the isolation of pure **16**. Using the optimized reaction conditions, the crotylation

reaction could be performed on a 50 gram scale to provide the silyl ether (**16**) in 75% yield over 2 steps.

After successful installation of the first two stereocenters, our attention focused on elaboration of the terminal alkene in **16**. Treatment with disiamylborane followed by oxidative work up afforded primary alcohol **17** in good yields (70–85%).<sup>20</sup> Subsequent oxidation of the primary alcohol **17** using Dess-Martin periodinane<sup>21</sup> gave the desired aldehyde in a quantitative yield, which then was carried through the Pinnick oxidation<sup>22</sup> to afford carboxylic acid **19**.

The stage was now set for the convergent coupling with a  $\beta$ -stannyl enamine linchpin. Starting from pentynyl chloride **12**, a Gabriel amine synthesis was utilized to form primary amine **20** in 85% yield (Scheme 3).<sup>23</sup> The protecting group on the amine was formed via transimination with benzophenone imine to form imine **11a**.<sup>24</sup> The protecting group on the nitrogen could be varied and is an important aspect for success of the free-radical mediated amination and future deprotection reaction (*vide infra*).

Free radical-mediated aminostannation was carried out using slow addition of  $^n\text{Bu}_3\text{SnH}$  and AIBN to a refluxing, degassed benzene solution of imine **11a** (Scheme 3).<sup>14</sup> The stannane radical adds to the terminal position of the alkyne (as in **21a**) to form the vinyl radical (**21b**). The 5-*exo-trig* cyclization of the vinyl radical onto the azomethine nitrogen provides a stabilized tertiary carbon radical adjacent to two phenyl groups (**21c**).<sup>25</sup> This radical is quenched by excess  $^n\text{Bu}_3\text{SnH}$  to form  $\beta$ -stannylamine **9a**, which is used in unpurified form for the subsequent coupling reaction with acid chloride **8**.

The acid chloride needed for the coupling was made by treating acid **19** with oxalyl chloride (Scheme 4). After removal of volatile compounds, the crude acid chloride **8** was added to the  $\beta$ -stannyl enamine (**9a**) and the resulting oil was chromatographed to provide the coupled product (**7a**). Vinylogous amides (**7b**, **7c**, and **7d**), with different *N*-protecting groups, were synthesized utilizing the same protocol with  $\beta$ -stannyl enamines (**9b**, **9c**,<sup>14c</sup> and **9d**, respectively).

With vinylogous amides **7a–d** in hand, the intramolecular conjugate addition was attempted (Table 1). Various methods were initially investigated to effect the deprotection/cyclization using diphenylmethyl (DPM)-protected **7a**, such as complexation with Lewis acids with or without hydride reducing agents (entries 3–8) and metal-catalyzed reduction (entries 1–2).<sup>19b</sup> These reactions either did not occur or caused deprotection of the TBS group (to form **22b**). Oxidative removal of the *N*-protecting group using DDQ led to cleavage of the vinylogous amide to form lactam **22c** (entry 9). Oxidative deprotection methods attempted with the other vinylogous amides (**7b–7d**) also resulted in lactam **22c** (entries 10, 12, 21). Using CAN instead of DDQ provided the most interesting results with both **7b** (entry 11) and **7d** (entry 22). In both cases, the *N*-deprotection was successful and the ketone by-product was observed (bis(PMP) ketone in entry 11 and PMP-CH<sub>3</sub> ketone in entry 22) but none of the deprotected product could be isolated (**22a**). Fortunately, using CAN with substrate **7d** (entry 22) provided the desired, cyclized product (**6**).

Only one diastereomer of the product (**6**) was observed and this was expected based on examination of the interactions within the transition state (Scheme 5). Developing A<sup>1,3</sup>-strain between the large ethyl acetate substituent and the nitrogen protecting group in pre-transition state assembly *a* would disfavor the ethyl ester substituent in the equatorial position (**23a**). Alternatively, pre-transition state *b* containing the axial ester would minimize this strain between the ester and the pyrrolidine ring and also between the vinyl hydrogen and large OTBS group (**23b**). NOE studies were performed on the isolated product (**6**) to

confirm the stereochemistry of the ester side chain as well as those created by the Brown crotylation. The vinylogous amide was established as *Z* based on an NOE correlation between the equatorial hydrogen and a methylene of the pyrrolidine ring. Furthermore, the chair conformation of the cyclohexanone ring in solution was determined based on coupling constant analysis. Under optimal conditions, the desired vinylogous amide could be isolated in up to 46% yield.

The next desired step was the installation of an allyl group which would provide the three carbons in the piperidine ring of serratezomine A. However, exposure of vinylogous amide **6** to a variety of bases (LDA, KO<sup>t</sup>Bu, KHMDS, <sup>n</sup>BuLi) and allyl halides did not provide any of the desired substrate (**25**, Scheme 6). Under all conditions, either starting material was recovered or a new product was formed containing a strong UV active  $\pi$ -system and led to assignment of the new product as vinylogous imide **26**. The reaction gave the highest yield when using NaH and THF (80% yield) but can also occur simply by chromatography of **6** on Et<sub>3</sub>N-treated silica gel.

A plausible mechanism for formation of imide **26** is outlined in Scheme 7. Deprotonation of the acidic pyrrolidine nitrogen in vinylogous amide **6** would lead to enolate **27a**. Rotation about the C-C  $\sigma$ -bond, nucleophilic attack by the vinylogous amide on the ester, and a cyclohexanone ring flip leads to **27b**. This ring flip locates the nitrogen in proximity to the ester side chain allowing for cyclization to form imide **26**. The fact that the transformation occurs on SiO<sub>2</sub> treated with Et<sub>3</sub>N suggests the importance of base to enhance the nucleophilicity of the nitrogen N-H.

While this reaction course was unplanned, imide **26** appeared to be a viable intermediate to serratezomine A (**1**). Imide **26** was more stable over time, compared to **6**, and provided a rigid, tricyclic structure that might also be advanced to serratezomine A. A comparison of the two routes is shown in Scheme 8 (new = route 1, original = route 2).<sup>26</sup> For route 1, a reductive allylation (e.g. dissolving metal reduction) of vinylogous imide **26** would furnish **28**. The amide bond could act as a protecting group for the nitrogen until cyclization to form the piperidine ring was necessary, at which time the amide would be solvolyzed. Alternatively, if route 2 using vinylogous amide **6** was applied, then the ester functionality would have to be reduced prior to allylation to prevent imide formation (as in **29**). With **29** in hand, allylation would provide **30**. Both routes address the installation of the congested quaternary carbon, which we anticipated would be among one of the most challenging aspects of the synthesis – unusually so for serratezomine A relative to other *Lycopodium* alkaloids due to its axial alcohol at C8. During the early studies investigating Route 2, any reagents used to effect ester reduction still proved too basic and instead caused cyclization to imide **26**. At that point, the decision was made to investigate Route 1.

### Claisen Approach to Establish the C12 Quaternary Stereocenter (Route 1)

To progress forward with this route, an allyl group would need to be installed adjacent to the ketone, as in **28**. Alkene reduction of **26** and a subsequent allylation provided a feasible sequence that might be adapted to a one step process.<sup>27</sup> Alkene reduction was achieved using metal-catalyzed hydrogenation on either vinylogous amide **6** or imide **26** (Scheme 9). Hydrogenation of **6** over Pd/C provided a 56% yield of ketone **31** while PtO<sub>2</sub> provided over-reduction of the ketone as well (to form the  $\alpha$ -OH, not shown).<sup>28</sup> Alternatively, imide **26** could be reduced using catecholborane in the presence of Wilkinson's catalyst to form ketone **31**.<sup>29</sup> Gratifyingly, the pyrrolidine stereocenter in both reductions was set in the correct orientation as is required in serratezomine A, indicating that substrate control provided the needed configuration.<sup>30</sup>

The stereocenter of the hydrogen adjacent to the ketone in **31**, however, is opposite to that of the desired allyl group (as in **28**). Epimerization was possible in the presence of bases that established thermodynamic conditions, such as NaH or <sup>t</sup>BuOK, to provide the ketone epimer with a *cis*-orientation of the 6,6-ring system (**32**, Scheme 9). Epimer **32** could also be formed in one step using a solution of lithium in NH<sub>3</sub> (**26** → **32**). If allylation could occur from the same face as protonation (see **28**), then successful installation of the quaternary center would be achieved. However, attempts to capture the enolate with allyl halides and a variety of bases did not result in any *C*-allylation (**28**) starting from either ketone epimer (**31** or **32**). Small amounts of *O*-allylated product **33** were isolated though and could be enhanced using KO<sup>t</sup>Bu and HMPA (61% yield). Allyl vinyl ether **33** is significant since it could potentially be converted to the desired allylation product (**28**) via a Claisen rearrangement.

Pursuing this course, ether **33** was heated to 170 °C in a sealed tube. While the reaction was successful, it provided the undesired allyl epimer with the *trans*-decalone ring system (**34**, Scheme 10). The key NOESY correlation used in assigning the configuration was the 1,3-diaxial interaction between the geminal hydrogen to the OTBS group and one of the hydrogens of the methylene carbon in the allyl group. Modeling studies using Pmodel showed that while the energy difference between non-allylated *trans*-decalone **31** and *cis*-**32** was relatively small (0.13 kcal/mol), the difference between allylated *trans*-decalone **34** and *cis*-**28** is much greater (2.4 kcal/mol) with *trans*-**34** being favored. Inspection of the bond angles in each 6-membered ring showed that the cyclohexanone ring suffered the most torsional strain in *cis*-decalone **28** due to the allyl group. This would explain why capture of a proton is possible to form the *cis*-decalone (**32**) but allylation in this same manner was never observed (**28**). It appeared that substrate control would not be easily overcome to obtain the desired allylation product. This realization encouraged us to further consider Route 2 involving reduction of the ester to prevent cyclization to form imide **26** (see Scheme 8 for comparison of the two routes).

### Oxidative Allylation Approach to Establish the Quaternary Stereocenter at C12 (Route 2)

To explore Route 2, the ester in **6** would need to be reduced to prevent the cyclization to the imide. As mentioned, many reducing agents were also sufficiently basic, causing cyclization to imide **26** (even NaBH<sub>4</sub>/CeCl<sub>3</sub>). The key reducing agent was eventually identified as Red-Al in toluene. It allowed reduction of the ester to form **35** which was then protected as pivalate **36** in good yield (Scheme 11).

Different allylation reaction conditions were then attempted to install the three carbon chain necessary to form the piperidine ring. These attempts focused on various base-mediated alkylation reactions, but were not successful despite the possibility of *N*, *C*, or *O*-alkylation. Even metal-catalyzed hydrogenation, which worked well with imide **26**, did not work to provide any alkene reduction (in which an allyl group would be added in a second step). Unreacted starting material was isolated in all cases (**36** → **37**, Scheme 11). Interestingly, if the allyl halide was exposed to Ag(I) salts, small amounts of allylated products were observed which indicates that the vinylogous amide is inherently nucleophilic. An attempt to capitalize on this behavior was tested via exposure of **36** to two oxidants, NCS<sup>31,32</sup> and MCPBA, providing the α-chloro ketimine (**38**) and α-hydroxy ketimine (**39**), respectively.<sup>33</sup>

Both **38** and **39** were reasonable substrates to allow introduction of an allyl group by reductive enolate formation.<sup>34</sup> However, exposure of either compound to SmI<sub>2</sub> and allylbromide provided intractable mixtures. The use of either Fe(acac)<sub>3</sub><sup>35</sup> or HMPA<sup>36</sup> provided a cleaner reaction, but no allylated product (**37**) was observed and only reduced

vinylous amide **36** was isolated. This demonstrates that the  $\alpha$ -carbon-heteroatom bond was reductively cleaved, but protonation followed rather than allylation.

The insight gained from exposure of **36** to oxidants led us to the successful work from the Flowers' group utilizing a cerium-mediated oxidative allylation of vinylous amides.<sup>37</sup> Their research used a more soluble source of Ce(IV) known as CTAN<sup>38</sup> ( $\text{Ce}(\text{NBu}_4)_2(\text{NO}_3)_6$ ) along with allyl silane as the source of the three carbon chain. Initial allylation attempts using CTAN, allyl silane, and vinylous amide **36** furnished a *C*-allyl product in only 20% yield. However, 2D NMR analysis indicated the product was the desired diastereomer (**37**, Scheme 12). Optimization included increasing the amount of allyl silane to two equivalents (45% yield) and degassing the  $\text{CH}_3\text{CN}$  solvent (55% yield). Degassing of  $\text{CH}_3\text{CN}$  likely improved the reaction because oxygen can react with a radical intermediate, leading to oxidation byproducts (one of which was identified as  $\alpha$ -hydroxyketone **39**). A further improvement was made by switching CTAN to CAN which gave the highest yields (58–67%) and diastereoselection (23:1, assigned based on isolation of the minor diastereomer on large scale, *epi*-**37**).

The mechanism of the oxidative allylation is believed to involve single electron oxidation of the vinylous amide (**36**) by cerium(IV), forming radical cation **40a** (Scheme 13).<sup>37a,39</sup> The radical cation then undergoes attack by the nucleophilic allyl silane, forming the quaternary center and a new secondary alkyl radical (**40b**). A second equivalent of Ce(IV) is then needed to oxidize the radical to a cation (**40c**). It was then proposed by the Flowers group that the nucleophilic solvent,  $\text{CH}_3\text{CN}$ , plays a role in displacement of the trimethylsilyl group, providing the terminal alkene in **37**.<sup>37a</sup>

The high diastereoselectivity observed during the allylation is surprising (Scheme 13). It is likely that the cyclohexanone ring flip occurs as soon as the radical cation is formed since the  $\pi$ -bond of the alkene in **36** is broken, resulting in the release of  $A^{1,3}$ -strain (*vide infra*) and allowing the large OTBS group to be equatorial. The main interactions an incoming allyl silane nucleophile would experience from the bottom face are a 1,2-interaction with an axial hydrogen in **40a**. From the top face, there would be two 1,3-diaxial interactions with hydrogen and a 1,2-interaction with the side chain in **40a**.

The all-carbon quaternary stereocenter was now established and all carbons required in serratezomine A were in place. Our attention was then turned to accessing the piperidine ring by functionalizing the terminal alkene via hydroboration. To prevent selectivity issues, the ketone had to be reduced prior to hydroboration in which the  $\beta$ -alcohol was required as in the natural product. Reduction with  $\text{NaBH}_4$  in THF at room temperature provided more of the undesired  $\alpha$ -alcohol in yields ranging from 45–58% (not shown), likely due to an imine directed borane delivery to the top face. To direct hydride addition to the opposite face, chelating conditions were used to engage the imine nitrogen and ketone since this would effectively block the top face. Gratifyingly, using a bidentate Lewis acid ( $\text{Et}_2\text{AlCl}$ ) and  $^t\text{Bu}_3\text{SnH}$  as a reducing agent afforded the desired  $\beta$ -alcohol in good yield and moderate diastereoselectivity (**41**, Scheme 14).<sup>40</sup> Rapid addition of  $^t\text{Bu}_3\text{SnH}$  resulted in the simultaneous reduction of the ester to afford the diol (**42**) with similar diastereoselectivity. A two-step reduction/deprotection to diol **42** was also developed using the chelating reduction in the first step and then sodium metal in MeOH for the second step. The two-step protocol was advantageous since the alcohol diastereomers ( $\alpha$  and  $\beta$ -**41**) could be separated by column chromatography after the reduction, whereas it was not straightforward to separate the diol diastereomers ( $\alpha$  and  $\beta$ -**42**).

Having  $\beta$ -diol **42** in hand led us to attempt lactone ring formation, which would be followed by piperidine ring construction in separate synthetic operations. However,

subjecting diol **42** to a variety of oxidation conditions including  $\text{Ag}_2\text{CO}_3/\text{C}_6\text{H}_6$  (Fetizon oxidation),<sup>41</sup> Dess-Martin, PCC, and TEMPO proved fruitless, as no oxidation products were observed (**43**, Scheme 14). This was surprising since diol **42** is in the correct chair conformation to undergo lactonization. Our suspicion was that the nucleophilic imine nitrogen might be involved in the formation of side products that result once the primary alcohol in **42** is oxidized.<sup>42,43</sup>

Our attention was again focused on construction of the piperidine ring before the lactone ring. This would functionalize the nitrogen and allow us to proceed with the synthesis. Treatment of the alkene in **41** with either  $\text{BH}_3\cdot\text{THF}$  or  $\text{BH}_3\cdot\text{DMS}$  followed by oxidative work-up provided the desired primary alcohol **44**, but in low yields (23–35% with up to 25% recovered **41**, Scheme 15). A survey of boron reagents, including 9-BBN, disiamyl borane, and catechol borane with Wilkinson's catalyst  $[\text{RhCl}(\text{PPh}_3)_3]$ , did not provide the desired hydroboration product (**44**). Increasing the borane amount, reaction time, or temperature proved to be even more detrimental to the yield. We thought that the imine may be binding irreversibly to the borane, so Lewis acids were added along with the borane. The primary alcohol was still formed but without any improvement in the yield. Therefore, an alternative approach was used in which electrophilic bromination to form the piperidine ring directly via a bromonium intermediate and 6-*endo* cyclization (as in **47**). Instead a 5-*exo* cyclization was observed in the presence of NBS in either  $\text{CH}_2\text{Cl}_2$  or MeOH to form **45**.<sup>44</sup> Efforts to reduce the iminium ion with  $^n\text{Bu}_3\text{SnH}$  or  $\text{NaBH}_3\text{CN}$  were unsuccessful but did reduce the primary bromide in the former case. There is literature precedence for conversion of the 5-*exo* to 6-*endo* product via an intermediate aziridium ion (**45**→**47**), but attempts to implement this approach were met with failure, likely due to the inability to reduce the iminium ion in **45**.<sup>45</sup>

Despite low yields during the hydroboration, alcohol **41** provided our best access to serratezomine A and was carried forward to form the piperidine ring. Conversion of the alcohol to the primary bromide was successful using  $\text{Br}_2$  and  $\text{PPh}_3$  (**48**, Scheme 16). After column chromatography to isolate bromide **48**, a second compound of low  $R_f$  was also observed that was not initially seen by  $^1\text{H}$  NMR analysis of the crude reaction mixture. This compound would form by allowing a pure sample of bromide **48** to stand at room temperature in  $\text{CDCl}_3$ . Surprisingly, the compound was not only cyclized to form the piperidinium ring, but was also epimeric at the quaternary center and was identified as *epi*-**49** instead of the expected product (**49**).

To ascertain the structure of *epi*-**49**, it was subjected to a  $\text{PtO}_2$ -catalyzed reduction to provide the amine as a single diastereomer (**50**, Scheme 17). At this point 2D NMR techniques more clearly highlighted the correlations with the new methine CH adjacent to the nitrogen.<sup>46</sup> Fortunately, a crystal structure of *epi*-**49** was also obtained by exchange of the bromide counterion to a triflate (using  $\text{TESOTf}$ , **51**). The crystal structure unambiguously confirmed the epimerization and solidified our previous stereochemical assignments. The epimerization likely occurs through an enamine *retro*-aldol reaction of the expected cyclized product (**49**) (as in Scheme 17).<sup>47</sup> First, a ring opening of **49** forms the enamine-aldehyde (**52a**). Rotation about the C-C  $\sigma$ -bond in **52a** provides intermediate **52b** in which enamine addition to the aldehyde to reclose the ring would give **52c**. After protonation of the enolate, *epi*-**49** would result with an overall epimerization of the spirocyclic carbon.

The driving force to epimerize is less apparent. The isomerization may relieve some strain derived from the interaction of the methylene carbon in the pyrrolidine ring with the two axial hydrogens on the cyclohexanol ring in **49**. The epimerized product (*epi*-**49**) allows the pyrrolidine ring to be further away and thus minimizes the steric strain. The epimerization

was an unfortunate finding so late in the synthesis but seems to be favored based on substrate control. Several routes were then devised to prevent epimerization; reduction of the imine (to prevent formation of an iminium ion upon cyclization), protection of the  $\beta$ -OH (to prevent opening of the cyclohexanone ring), and formation of the  $\alpha$ -OH (as an alternative strategy). The latter two are discussed here.

### Routes Investigated to Prevent Epimerization

Protection of  $\beta$ -alcohol **41** was unexpectedly complicated. While silylation was successful (TESOTf or TIPSOTf), the addition of a larger protecting group, along with the fact that four of the six substituents were axial, provided compounds with broad peaks by NMR analysis and unclear conformational preferences. An idea to tether the  $\beta$ -OH with the primary alcohol, using diol **42**, was also met with failure.<sup>48</sup> A crystal structure of diol **42** was obtained, which revealed that a hydrogen bond existed between the imine nitrogen and the secondary alcohol (Figure 2). This could explain the observed unreactivity of the  $\beta$ -alcohol towards protecting group reaction conditions.

Fortunately, the sulfonation of the alcohol could be accomplished to form mesylate **53** in quantitative yield (Scheme 18). In an effort to increase the yield of the next step – hydroboration of the alkene – two tactics were pursued. The first was deprotection of the TBS group since it was speculated that the terminal alkene was sterically hindered by the large TBS group, thus leading to low yields of the primary alcohol. Treatment of **53** with TBAF at 66 °C provided an unexpected product, the bridged bicyclic ether (**54**) as a result of an intramolecular  $S_N1$  displacement of the mesylate by the intermediate alkoxide formed from the TBS deprotection.

The second attempt to increase the yield of the hydroboration was to locate the mass balance. During chromatography, more polar fractions were present and accounted for 35–40% of the material. <sup>1</sup>H NMR analysis revealed a set of broad peaks different from the primary alcohol. Upon storage of this viscous oil for several days, the new compound converted to primary alcohol **55**. It was speculated that the broadness of the peaks may be a result of borane binding with the electron rich imine (as in **56**, Scheme 18). Furthermore, amine-borane complexes are known to be stable and isolable compounds at room temperature.<sup>49,50</sup> To test this hypothesis, a solution of the oil (presumed to be **56**) in CH<sub>2</sub>Cl<sub>2</sub> was treated with an excess of DMAP for 7 days. DMAP, an electron rich amine, was expected to bind more strongly to borane than to the imine functionality, and thus would act as a borane scavenger. Indeed, purification of the resulting mixture afforded the pure primary alcohol (**55**). This study established the feasibility of alkene conversion to the terminal alcohol, but concerns related to sulfonate deprotection<sup>51</sup> and our inability to make forward progress with  $\beta$ -alcohol (**41**) led us to a new approach to serratezomine A, using the  $\alpha$ -alcohol.

Originally, the  $\beta$ -alcohol was desired as an approach to lactone ring formation but our numerous strategies were thwarted (*vide supra*). Since the alcohol was easily protected as the mesylate, it was envisioned that the  $\alpha$ -mesylate could be used instead (**57**, Scheme 19).<sup>52</sup> Conversion of **57** to the piperidine ring could be accomplished in a similar manner as before to form **58**. Then a pivalate deprotection could be carried out and the primary alcohol could be oxidized to a carboxylate (as in **59**). Cyclization of the carboxylate could occur via an  $S_N1$  displacement of the mesylate to form the lactone ring, leaving only a TBS deprotection to complete the synthesis of **1**.

### Advancement of the $\alpha$ -alcohol as a new strategy

To form the desired alcohol, ketone **37** was treated with NaBH<sub>4</sub> in THF to provide the  $\alpha$ -alcohol (**60**, >23:1 dr) which was then protected as the mesylate in excellent yield (**57**, Scheme 20). The mesylate was subjected to the hydroboration conditions, and the resulting crude oil was treated as before with DMAP. Upon purification, the desired primary alcohol (**61**) was isolated. The alcohol was again treated with Br<sub>2</sub> and PPh<sub>3</sub> to afford the primary bromide, which cyclized slowly upon standing to afford the iminium salt (**62**). Subsequent reduction of iminium **62** was investigated by utilizing both hydride reducing agents and metal-catalyzed hydrogenation. The latter case proved superior in providing the amine (**58**). The <sup>1</sup>H NMR peaks of **58** were uniformly broad, suggesting two interconverting chair conformations as shown. As a result, 2D NMR analysis to determine the facial selectivity of the reduction step could not be conducted. However, the presence of only one set of peaks in the NMR strongly suggested the reduction was highly stereoselective to provide the desired isomer, as a *syn*-pentane interaction between the pyrrolidine ring and ester side chain would highly disfavor the undesired isomer.<sup>53</sup>

With the piperidine ring in place (**58**), our attention turned towards oxidative adjustment of the primary alcohol to the carboxylate functionality to allow formation of the lactone ring. To accomplish this goal, deprotection of the pivalate protecting group was required. Treatment of **58** with DIBAL afforded the desired alcohol in good yield (**63**, Scheme 21). The alcohol was then subjected to a variety of oxidation conditions including Dess Martin periodinane, Parikh-Doering,<sup>54</sup> and Swern oxidations. In all cases, decomposition of the starting material was observed and no oxidation product could be isolated (**64**). It was believed that the lone pair of electrons on the nitrogen still exerted its effect by donating into the newly formed aldehyde, and that the resulting strained hemiaminal underwent a variety of fragmentation pathways, leading to the decomposition of **64**.<sup>43</sup>

It was reasoned that serratezomine A might be accessed by a RuO<sub>4</sub>-mediated oxidation of cyclic ether **65**.<sup>55</sup> The approach to **65** appeared straightforward via an intramolecular S<sub>N</sub>i displacement of the mesylate by an alkoxide, generated by deprotonation of the primary alcohol. Surprisingly, alcohol **63** was inert to most basic reaction conditions including potassium *tert*-butoxide, sodium hydride, LiHMDS and LDA (Scheme 21). Exposure to <sup>n</sup>BuLi and <sup>t</sup>BuLi led to complete decomposition of the starting material. Based on the model studies, it was believed that the steric interactions between the two sp<sup>3</sup>-hybridized carbons at C5 and C15 were too high to overcome in the cyclic ether (**65**). The S<sub>N</sub>2 displacement of the mesylate by an exogenous oxygen nucleophile was also investigated to form diol **66**. It was hypothesized that the presence of the  $\beta$ -alcohol in diol **66** would lead to the formation of the desired lactone, via a lactol intermediate, using a Fetizon oxidation. The mesylate was treated with a variety of oxygen nucleophiles, including CsOAc,<sup>56</sup> <sup>n</sup>Bu<sub>4</sub>N<sup>+</sup>-NO<sub>3</sub>,<sup>57</sup> and KNO<sub>2</sub><sup>58</sup> at elevated temperatures (>100 °C) and for a long duration (10–20 hours). However, the starting material was recovered in all cases. The inert nature of mesylate **63** could be attributed to its sterically hindered environment (both the adjacent quaternary center and the axial alcohol side chain).

### Completion of the Synthesis and Reduction of the Overall Step Count

The use of an  $\alpha$ -mesylate remained a promising strategy and we encountered difficulties only during the late-stage oxidation in an attempt to form the lactone ring. This could be avoided if the pivaloate side chain was not reduced to the alcohol earlier in the synthesis (refer to Scheme 11). The ester reduction was used at the time to prevent formation of the tricyclic imide under basic conditions. With the cerium-mediated allylation developed, it was hypothesized that the product might withstand the non-basic conditions and not undergo an undesired cyclization, thereby reducing the total step count by two.

The CAN-mediated oxidative allylation of vinylogous amide **36** was carried out as before, but now with the ethyl ester in place to form **25** (Scheme 22). Fortunately, no cyclization of the imine onto the pendant ester was observed in the product (**67**) and the high diastereoselectivity for the allylation was maintained. The ketone was then treated with an excess of NaBH<sub>4</sub> in THF to form the  $\alpha$ -alcohol (**68**). The reaction was sluggish, but ultimately provided the desired alcohol in high diastereoselectivity (>20:1), albeit in low yields (**68**, Table 2, entry 1). In an attempt to increase the yield of the reduction step, a variety of reducing agents and reaction conditions were evaluated. Employing KBH<sub>4</sub>, LiBH<sub>4</sub> and *L*-Selectride as reducing agents afforded  $\alpha$ -alcohol **68** in high diastereoselectivity but with mainly decomposition of the starting material (entries 4–7). Gratifyingly, treatment of ketone **25** with NaBH<sub>4</sub> in MeOH led to complete conversion to  $\alpha$ -alcohol **68**, but in low diastereoselectivity (entry 2). The solvent that ultimately provided the best combination of diastereoselectivity and yield was 1-propanol (entry 3). Performing the reaction at lower temperatures did not improve the diastereoselection in favor of the  $\alpha$ -alcohol.<sup>59</sup>

With the ketone reduction in place, we turned towards formation of the piperidine ring. After some experimentation, we were pleased to find that the desired iminium salt could be formed in quantitative yield by mesylation of the primary alcohol, rather than formation of the corresponding bromide, followed by imine cyclization. After extended treatment of the reaction mixture with aqueous NH<sub>4</sub>Cl, the crude NMR indicated complete conversion and cyclization to the iminium salt (**71**, Scheme 23). The crude reaction mixture was then treated with NaBH<sub>3</sub>CN to afford the tertiary amine (**72**) in quantitative yield.<sup>60</sup> The NMR peaks of **72** were uniformly broad, as in **58**, but indicated one diastereomer at C4 had formed and this was carried onto the next step.

The final efforts were focused on installing the bridged lactone by a tandem saponification/intramolecular S<sub>N</sub>i cyclization strategy (Scheme 23). Employing different reagents for the saponification including NaOTMS,<sup>61</sup> K<sub>2</sub>CO<sub>3</sub>,<sup>62</sup> and LiOH led to either decomposition or formation of an alkene by facile elimination of the mesylate (**74**). Success was finally realized by treating **72** with aqueous NaOH at 34 °C for 10 h to afford a 1.1:1 mixture of lactone **73** and alkene **74**, as indicated by NMR analysis. Purification attempts of the crude mixture were unsuccessful due to co-elution of the products. Therefore, the crude reaction mixture was instead exposed to TBAF at 40 °C for 20 h which led to a separable 3:2 mixture of (+)-serratezomine A (**1**) and the fused lactone (**75**, from lactonization of **74**). The spectral data (<sup>1</sup>H NMR, <sup>13</sup>C NMR, and IR) and optical rotation of synthetic **1** (syn. [ $\alpha$ ]<sub>D</sub> +9.5 (c 0.3, MeOH)), were in agreement with the reported values (nat. [ $\alpha$ ]<sub>D</sub> +13.0 (c 0.5, MeOH)), confirming the structural and absolute stereochemical assignments of **1** (for the complete, total synthesis scheme of **1**, see Scheme 24).

## CONCLUSIONS

In summary, the first total synthesis of (+)-serratezomine A was ultimately accomplished in 15 steps from a commercially available aldehyde. Notably, this is the only member of the *Lycopodium* alkaloids of the fawcettimine class bearing a substituent (OH) at C8 to be prepared other than the early synthesis of serratinine. The axial alcohol provided a powerful driving force for quaternary carbon epimerization when offered a pathway (**49**→*epi*-**49**). Fortunately, this challenge was overcome without sacrificing brevity in the current synthesis, but did require several investigational lines to probe the reactivity inherent to this crowded system. Additional salient features of this synthesis include: (a) application of a free radical-mediated vinyl amination to construct the pyrrolidine ring; (b) a highly stereoselective intramolecular Michael addition to construct the cyclohexane ring; (c) the use of an oxidative allylation promoted by cerium(IV) to establish the all carbon quaternary stereocenter with the proper configuration; (d) a tandem saponification/intramolecular S<sub>N</sub>i

cyclization to provide the bridged lactone; and (e) minimal use of protecting groups. Access to the  $\beta$ -stannyl enamine was particularly enabling, as it provided a platform for the convergent assembly of each unit in a sequence of three steps.

## EXPERIMENTAL SECTION

### General Methods

All glassware used for reactions was flame-dried under vacuum and reactions were run under an inert atmosphere of nitrogen or argon. All reagents and solvents were commercial grade and purified prior to use when necessary. Diethyl ether (Et<sub>2</sub>O), tetrahydrofuran (THF), dichloromethane (CH<sub>2</sub>Cl<sub>2</sub>), benzene (C<sub>6</sub>H<sub>6</sub>), and acetonitrile (CH<sub>3</sub>CN) were dried by passage through a column of activated alumina as described by Grubbs.<sup>63</sup> Benzene was additionally passed through a column containing activated Q-5 reactant. All other solvents were distilled over calcium hydride before use or are otherwise indicated differently. All organic layers collected from extractions were dried over MgSO<sub>4</sub> unless otherwise indicated. Reagents were used from the bottle unless otherwise noted within the experimental details. Thin layer chromatography (TLC) was performed using glass-backed silica gel (250  $\mu$ m) plates and flash chromatography utilized 230–400 mesh silica. Products were visualized using UV light and either ceric ammonium molybdate, ninhydrin, *p*-anisaldehyde, potassium iodoplatinate, or potassium permanganate solutions. Melting points were recorded on a capillary melting point apparatus and are reported uncorrected. For FTIR, liquids and oils were analyzed as neat films on a NaCl plate (transmission), whereas solids were applied to a diamond plate (ATR) if a thin film could not be prepared, and data are reported in wavenumbers (cm<sup>-1</sup>). NMR were acquired on either a 400, 500 or 600 MHz instrument. Chemical shifts are measured relative to the residual solvent peaks as an internal standard set to  $\delta$  7.26 and  $\delta$  77.1 for <sup>1</sup>H and <sup>13</sup>C, respectively. Multiplicities are reported as singlet (s), doublet (d), triplet (t), quartet (q) or combinations thereof while higher coupling patterns are written out explicitly. HRMS data was obtained either by chemical ionization (CI), electron ionization (EI), or electrospray ionization (ESI) using an ion trap or by matrix-assisted laser desorption/ionization (MALDI) in either positive and negative ion modes using TOF. Combustion data analyzing C, H, and N were performed on select compounds. Compounds **5**, **7d**, **14**, **16**, **25**, **68**, **69**, **70**, and **72** were reported in an earlier publication<sup>8</sup> as well as **9c** and **11c**.<sup>14c</sup>

**(+)-Serratezomine A (1) and (1S,5S,6S,7S,8'S,8a'R)-6-((tert-Butyldimethylsilyl)oxy)-7-methylhexahydro-1'H-2-oxaspiro-**

**[bicyclo[3.3.1]nonane-9,8'-indolizin]-3-one (73)**—To a solution of ester **72** (13.2 mg, 25.5  $\mu$ mol) in MeOH (600  $\mu$ L) at 0 °C was added sodium hydroxide (220  $\mu$ L, 0.1 M in H<sub>2</sub>O). The reaction was stirred for 30 min before being warmed to 34 °C and stirred for another 10 h. The solvent was removed *in vacuo* and the resulting residue was dissolved in CH<sub>2</sub>Cl<sub>2</sub>. The organic layer was washed once with H<sub>2</sub>O and then satd aq NH<sub>4</sub>Cl and dried, filtered, and concentrated to a yellow oil. The crude oil could be purified and was characterized as the TBS protected intermediate (**73**, see data below). Alternatively, the crude oil could be carried on directly by dissolving in THF (300  $\mu$ L) and adding TBAF (63.8  $\mu$ L, 1.0 M in THF). The reaction was stirred for 15 min before being warmed to 40 °C and stirred for another 20 h. The solvent was evaporated and the resulting crude oil was subjected to mass directed LC purification (15% CH<sub>3</sub>CN/0.1% TFA) to afford (+)-

serratezomine A **1** as a white solid (2.4 mg, 33%).  $R_f$  = 0.22 (10% MeOH/CH<sub>2</sub>Cl<sub>2</sub>);  $[\alpha]_D^{24}$  +9.5 (*c* 0.3, MeOH); IR (film) 3423, 2920, 2850, 1720, 1463, 1200, 1134 cm<sup>-1</sup>; <sup>1</sup>H NMR (400 MHz, MeOD)  $\delta$  4.32 (dd, *J* = 5.6, 2.8 Hz, 1H), 3.81 (dd, *J* = 11.2, 6.4 Hz, 1H), 3.77 (dd, *J* = 3.6, 3.6 Hz, 1H), 3.54 (ddd, *J* = 9.6, 9.6, 9.6 Hz, 1H), 3.36–3.34 (m, 1H), 3.28–3.25 (m, 1H), 3.14 (dd, *J* = 20.0, 8.0 Hz, 1H), 2.98 (ddd, *J* = 13.2, 13.2, 3.6 Hz, 1H), 2.83 (br d, *J*

**Ethyl 2-((1S,2R,3S,Z)-2-((tert-Butyldimethylsilyl)oxy)-3-methyl-5-oxo-6-(pyrrolidin-2-ylidene)cyclohexyl)acetate (6)**—Ceric ammonium nitrate (16.8 g, 30.6 mmol) was added in one portion to **7d** (8.10 g, 15.3 mmol) in  $\text{CH}_3\text{CN}/\text{H}_2\text{O}$  (5:1, 765 mL) at rt. After 5 min, the reaction was quenched with satd aq  $\text{NaHCO}_3$  and extracted with EtOAc. The combined organic layers were washed once with brine, and dried, filtered, and concentrated to an orange/brown oil. The crude oil was subsequently chromatographed ( $\text{SiO}_2$ , 10–32–38% ethyl acetate in hexanes) to provide **6** as a yellow/brown oil (2.8 g, 46%). This material was of sufficient purity to carry onto the next step, but to obtain an analytically pure compound for characterization, a second purification was performed ( $\text{SiO}_2$ , 35–50% ethyl acetate in hexanes) providing **6** as a dark yellow oil (2.5 g, 88% recovery, 40% after two purifications).  $R_f$  = 0.20 (50% EtOAc/hexanes);  $[\alpha]_D^{21}$  +50.0 ( $c$  1.0,  $\text{CHCl}_3$ ); IR (film) 2955, 2930, 2856, 1730, 1613, 1537  $\text{cm}^{-1}$ ;  $^1\text{H}$  NMR (500 MHz,  $\text{CDCl}_3$ )  $\delta$  10.75 (br s, 1H), 4.17 (dq,  $J$  = 10.9, 7.1 Hz, 1H), 4.10 (dq,  $J$  = 10.8, 7.1 Hz, 1H), 3.66 (br s, 1H), 3.59 (dt,  $J$  = 10.6, 6.9 Hz, 1H), 3.54 (dt,  $J$  = 10.6, 7.0 Hz, 1H), 2.95 (ddd,  $J$  = 9.4, 5.2, 2.8 Hz, 1H), 2.65–2.61 (m, 2H), 2.31–2.24 (m, 2H), 2.23 (dd,  $J$  = 17.0, 11.9 Hz, 1H), 2.18–2.05 (m, 2H), 2.05–1.96 (m, 2H), 1.26 (t,  $J$  = 7.1 Hz, 3H), 0.94 (d,  $J$  = 6.3 Hz, 3H), 0.81 (s, 9H), 0.05 (s, 3H), 0.03 (s, 3H);  $^{13}\text{C}$  NMR (125 MHz,  $\text{CDCl}_3$ ) ppm 194.7, 172.5, 167.8, 98.5, 72.6, 60.6, 47.7, 41.8, 41.0, 40.3, 30.6, 28.8, 25.9, 21.6, 18.7, 18.2, 14.4, –4.4, –4.8; HRMS (CI): Exact mass calcd for  $\text{C}_{21}\text{H}_{37}\text{NO}_4\text{Si}$   $[\text{M}]^+$  395.2486, found 395.2502. 1D NOE NMR studies to confirm the new stereocenter and to establish the alkene geometry are described in Supporting Information 2.

### General Procedure for the Coupling Reaction to Prepare Vinylogous Amides (7a–d)

The crude acid chloride (**8**, 1 equiv) was dissolved in THF (0.15 M), cooled to 0 °C, and then cannulated at a quick dropwise rate to a stirring solution of the  $\beta$ -stannyl enamine (**9a–9c** (1 equiv, small scale), **9d** (1.8 equiv, large scale) in THF (0.14 M) also at 0 °C. After the addition was complete, the reaction was allowed to stir an additional 5 min at 0 °C and was then warmed to rt and stirred overnight (10–14 h). The solvent was removed *in vacuo* and the crude oil was purified by column chromatography on  $\text{SiO}_2$  (0–40% ethyl acetate in hexanes) and the fractions containing the product were resubmitted to a second column with 20–35% ethyl acetate in hexanes) to provide the coupled product (**7a–d**).

**(2E,4S,5S,8E)-Ethyl 8-(1-Benzhydrylpyrrolidin-2-ylidene)-4-((tert-butyltrimethylsilyl)oxy)-5-methyl-7-oxooct-2-enoate (7a)**—According to the general coupling procedure, **9a** was treated with **8** to provide the vinylogous amide as a brown viscous oil which was chromatographed on  $\text{SiO}_2$  (5–50% ethyl acetate in hexanes) to provide **7a** as a pale orange oil (534 mg, 56% yield).  $R_f$  = 0.21, (30% EtOAc/hexanes); IR (film) 3063, 1638  $\text{cm}^{-1}$ ;  $^1\text{H}$  NMR: (400 MHz,  $\text{CDCl}_3$ )  $\delta$  7.34 (m, 6H), 7.13 (m, 4H), 6.87 (dd,  $J$  =

15.6, 4.6 Hz, 1H), 5.99 (s, 1H), 5.93 (dd,  $J = 15.6, 1.8$  Hz, 1H), 5.09 (s, 1H), 4.18 (m, 3H), 3.32 (t,  $J = 7.6$  Hz, 2H), 3.09 (t,  $J = 7.3$  Hz, 2H), 2.30 (dd,  $J = 14.5, 4.9$  Hz, 1H), 2.19 (m, 1H), 2.00 (m, 1H), 1.93 (t,  $J = 7.3$  Hz, 2H), 1.28 (t,  $J = 7.3$  Hz, 3H), 0.89 (s, 9H), 0.81 (d,  $J = 6.7$  Hz, 3H), 0.03 (s, 3H),  $-0.01$  (s, 3H);  $^{13}\text{C}$  NMR (100 MHz,  $\text{CDCl}_3$ ) ppm 196.3, 166.8, 165.3, 149.5, 138.5, 128.9, 128.8, 128.7, 128.1, 121.2, 91.6, 75.3, 63.3, 60.5, 49.9, 46.0, 36.9, 33.7, 26.1, 21.3, 18.4, 15.7, 14.5,  $-4.4$ ,  $-4.7$ ; HRMS (CI): Exact mass calcd for  $\text{C}_{34}\text{H}_{47}\text{NO}_4\text{Si}$   $[\text{M}]^+$ , 561.3274. Found 561.3291.

**(2E,4S,5S,8E)-Ethyl 8-(1-(Bis(4-methoxyphenyl)methyl)pyrrolidin-2-ylidene)-4-((tert-butyldimethylsilyl)oxy)-5-methyl-7-oxooct-2-enoate (7b)**—According to the general coupling procedure, **9b** was treated with **8** to provide the vinylogous amide as a brown viscous oil which was chromatographed on  $\text{SiO}_2$  (5–50% ethyl acetate in hexanes) to provide **7b** as an orange oil (241 mg, 28%).  $R_f = 0.11$ , (30% EtOAc/hexanes); IR (film) 2955, 1717  $\text{cm}^{-1}$ ;  $^1\text{H}$  NMR (400 MHz,  $\text{CDCl}_3$ )  $\delta$  7.03 (dd,  $J = 8.6, 1.3$  Hz, 4H), 6.88 (m, 5H), 5.94 (dd,  $J = 15.6, 1.6$  Hz, 1H), 5.88 (s, 1H), 5.07 (s, 1H), 4.18 (m, 3H), 3.80 (s, 3H), 3.30 (dd,  $J = 7.5, 7.5$  Hz, 2H), 3.06 (dd,  $J = 7.0, 7.0$  Hz, 2H), 2.30 (dd,  $J = 14.5, 4.8$  Hz, 1H), 2.20 (m, 1H), 2.01 (dd,  $J = 14.2, 9.1$  Hz, 1H), 1.90 (ddd,  $J = 14.7, 7.5, 7.5$  Hz, 2H), 1.28 (t,  $J = 7.0$  Hz, 3H), 0.89 (s, 9H), 0.82 (d,  $J = 6.7$  Hz, 3H), 0.03 (s, 3H),  $-0.01$  (s, 3H);  $^{13}\text{C}$  NMR (100 MHz,  $\text{CDCl}_3$ ) ppm 196.2, 166.8, 165.3, 159.3, 149.6, 130.9, 130.8, 129.8, 129.7, 121.2, 114.1, 91.3, 75.3, 62.1, 60.5, 55.5, 49.7, 46.0, 36.9, 33.8, 26.1, 21.2, 18.4, 15.7, 14.5,  $-4.3$ ,  $-4.7$ ; HRMS (CI): Exact mass calcd for  $\text{C}_{36}\text{H}_{51}\text{NO}_6\text{Si}$   $[\text{M}]^+$ , 621.3486. **(2E,4S,5S,8E)-Ethyl 4-((tert-Butyldimethylsilyl)oxy)-5-methyl-7-oxo-8-(1-(1-phenylethyl)pyrrolidin-2-ylidene)oct-2-enoate (7c)**—According to the general coupling procedure, **9c** was treated with **8** to provide the vinylogous amide as a brown viscous oil which was chromatographed on  $\text{SiO}_2$  (5–50% ethyl acetate in hexanes) to provide **7c** as a pale orange oil (436 mg, 69%).  $R_f = 0.10$  (30% EtOAc/hexanes); IR (film) 2955, 1718, 1544  $\text{cm}^{-1}$ ;  $^1\text{H}$  NMR (400 MHz,  $\text{CDCl}_3$ )  $\delta$  (unable to separate diastereomers) 7.35 (m, 2H), 7.28 (m, 1H), 7.22 (d,  $J = 7.3$  Hz, 2H), 6.90 (m, 1H), 5.97 (ddd,  $J = 15.6, 4.8, 1.6$  Hz, 1H), 5.17 (s, 1H), 4.95 (q,  $J = 7.0$  Hz, 1H), 4.11–4.27 (m, 3H), 3.32 (m, 2H), 3.18 (m, 1H), 3.08 (m, 1H), 2.36 (m, 1H), 2.25 (m, 1H), 2.07 (dd,  $J = 11.7, 9.1$  Hz, 1H), 1.88 (m, 2H), 1.57 (d,  $J = 7.0$  Hz, 3H), 1.28 (td,  $J = 7.3, 3.0$  Hz, 3H), 0.90 (s, 9H), 0.87 (m, 3H), 0.04 (s, 3H), 0.00 (s, 3H);  $^{13}\text{C}$  NMR (100 MHz,  $\text{CDCl}_3$ ) ppm 196.1, 166.9, 165.4, 149.7, 140.2, 129.0, 127.9, 126.9, 126.8, 121.3, 90.6, 75.4, 60.5, 53.2, 47.3, 46.1, 37.0, 34.0, 26.1, 21.1, 18.4, 17.0, 16.9, 15.8, 14.5,  $-4.3$ ,  $-4.7$ ; HRMS (CI): Exact mass calcd for  $\text{C}_{29}\text{H}_{45}\text{NO}_4\text{Si}$   $[\text{M}]^+$ , 499.3118. Found 499.3112.

**(4S,5S,E)-Ethyl 4-((tert-Butyldimethylsilyl)oxy)-7-chloro-5-methyl-7-oxohept-2-enoate (8)**—To carboxylic acid **19** (1 equiv) in  $\text{CH}_2\text{Cl}_2$  (0.1 M) at 0 °C was added oxalyl chloride (3 equiv). After several minutes, catalytic DMF was added (5–10  $\mu\text{L}$ ). The reaction was stirred for 30 min at 0 °C and 15 min at rt. The volatiles were removed *in vacuo* and the crude oil was placed under high vacuum for a short time and then used immediately in the coupling reactions above with **7a–7d**.

#### General Procedure for $\beta$ -Stannyl Enamine Formation (**9a–d**)

To a flame-dried round bottom flask fitted with a reflux condenser was added the alkynyl imine (**11a–11d**, 1 equiv) and the flask was evacuated and back-filled with nitrogen three times. Benzene (0.04 M in imine) and  $^n\text{Bu}_3\text{SnH}$  (0.22 equiv) were added and the contents were heated in an oil bath to 85–90 °C. In a separate flask, AIBN (1 equiv)<sup>64</sup> was added and the flask was evacuated and back-filled with nitrogen three times. Then benzene (0.25 M in imine) and  $^n\text{Bu}_3\text{SnH}$  (1.98 equiv) were added and the resulting solution was cannulated

through the reflux condenser of the original reaction vessel at rate of one drop every 3–4 sec. After the addition was complete, the reaction was stirred an additional 1 h before cooling to room temperature. The solvent was removed *in vacuo* to provide the crude  $\beta$ -stannyl enamines (**9a–d**) which were used in the coupling reaction with acid chloride **8**.<sup>65</sup> The scale varied between 1.5–15 mmol of **8**.

**(E)-Ethyl 4-oxobut-2-enoate (10)**—A 500 ml round bottom flask equipped with a magnetic stir bar and ozonolysis glass-adaptor fitting was charged with freshly distilled ethyl sorbate **13** (15 g, 0.107 mol) and absolute ethanol (430 mL). To this solution was added approximately 6 drops of a saturated solution of Sudan Red 7B dye in ethanol (resulting solution was magenta in color). The solution was cooled to  $-78^{\circ}\text{C}$  and then  $\text{O}_2$  was bubbled through the solution for ten minutes, followed by the addition of  $\text{O}_3$  until the solution turned a faint yellow color. At this point, the solution was purged with  $\text{O}_2$  for an additional 10 minutes. Dimethyl sulfide (approximately 2.2 equivalents) was then added dropwise at  $-78^{\circ}\text{C}$  and allowed to warm to rt overnight with stirring. The solution was concentrated, diluted with ether, washed with water and then satd aq  $\text{NaHCO}_3$ , and then dried ( $\text{Na}_2\text{SO}_4$ ), filtered, and concentrated. The residue was distilled ( $75^{\circ}\text{C}/15$  Torr) to give aldehyde **10** as a light yellow oil (13.7 g, 75%). All spectroscopic data was consistent with that reported in the literature.<sup>66</sup>

**N-(Diphenylmethylene)pent-4-yn-1-amine (11a)**—Alkynyl amine **20**<sup>67</sup> (3.5 g, 42.1 mmol), benzophenone imine<sup>24</sup> (7.25 g, 40.0 mmol), and 4 Å MS (2.0 g) were rapidly stirred in benzene (30 mL) at rt for 36 h. The solution was filtered through a pad of Celite, washed with ether, and concentrated to yield imine **11a** as a light yellow oil (9.76 g, 99%). IR (film) 3299, 3057, 1623  $\text{cm}^{-1}$ ;  $^1\text{H}$  NMR (400 MHz,  $\text{CDCl}_3$ )  $\delta$  7.64 (m, 2H), 7.46 (m, 3H), 7.36 (m, 3H), 7.19 (m, 2H), 3.48 (t,  $J = 6.7$  Hz, 2H), 2.33 (ddd,  $J = 7.3, 7.3, 2.7$  Hz, 2H), 1.92 (m, 3H);  $^{13}\text{C}$  NMR (100 MHz,  $\text{CDCl}_3$ ) ppm 168.7, 140.1, 137.1, 130.1, 129.0, 128.7, 128.6, 128.3, 128.0, 84.6, 68.6, 52.6, 30.3, 16.6; HRMS (CI): Exact mass calcd for  $\text{C}_{18}\text{H}_{16}\text{N}$  [ $\text{M}-\text{H}$ ]<sup>+</sup>, 246.1283, found 246.1283.

**N-(Bis(4-methoxyphenyl)methylene)pent-4-yn-1-amine (11b)**—Alkynyl amine **20**<sup>67</sup> (447 mg, 5.38 mmol), *p*-methoxybenzophenone imine<sup>68</sup> (865 mg, 3.60 mmol), and 4 Å MS (2.0 g) were rapidly stirred in benzene (10 mL) at rt for 48 h. The solution was filtered through a pad of Celite, washed with ether, and concentrated to yield imine **11b** as a light yellow oil (1.59 g, 96%). IR (film) 3297, 3002, 1604  $\text{cm}^{-1}$ ;  $^1\text{H}$  NMR (400 MHz,  $\text{CDCl}_3$ )  $\delta$  7.46 (d,  $J = 8.9$  Hz, 2H), 7.00 (d,  $J = 8.6$  Hz, 2H), 6.87 (d,  $J = 8.6$  Hz, 2H), 6.74 (d,  $J = 8.9$  Hz, 2H), 3.76 (s, 3H), 3.70 (s, 3H), 3.35 (dd,  $J = 6.7, 6.4$  Hz, 2H), 2.18 (m, 2H), 1.79 (m, 3H);  $^{13}\text{C}$  NMR (100 MHz,  $\text{CDCl}_3$ ) ppm 168.0, 161.3, 159.7, 134.2, 133.4, 132.5, 130.2, 129.6, 129.4, 128.6, 115.0, 114.0, 113.5, 84.7, 68.5, 55.6, 55.5, 52.5, 30.5, 16.6; HRMS (CI): Exact mass calcd for  $\text{C}_{20}\text{H}_{20}\text{NO}_2$  [ $\text{M}-\text{H}$ ]<sup>+</sup>, 306.1494, found 306.1484.

**(E)-N-(1-(4-Methoxyphenyl)ethylidene)pent-4-yn-1-amine (11d)**—Alkynyl amine **20**<sup>67</sup> (23.0 g, 270 mmol) was added to a flask containing *p*-methoxyacetophenone (27.0 g, 180 mmol) and 4 Å molecular sieves in  $\text{C}_6\text{H}_6$  (360 mL). After 24 h, the reaction was filtered through Celite using minimal  $\text{C}_6\text{H}_6$  and then more sieves were added and the reaction was stirred another 24 h. The reaction was filtered, more sieves were added and also more amine **20** (4 g) and the reaction was stirred 24 h, filtered, more sieves added, 24 h, then filtered and concentrated to a pale yellow oil. The crude oil (**11d**) contains less than 5% of the starting ketone (36.5 g, 94%). The imine was used crude below. IR (film) 3292, 2933, 1603, 1252  $\text{cm}^{-1}$ ;  $^1\text{H}$  NMR (500 MHz,  $\text{CDCl}_3$ )  $\delta$  7.65 (d,  $J = 8.9$  Hz, 2H), 6.78 (d,  $J = 8.9$  Hz, 2H), 3.72 (s, 3H), 3.43 (t,  $J = 6.7$  Hz, 2H), 2.27 (td,  $J = 7.0, 2.6$  Hz, 2H), 2.12 (s, 3H), 1.87 (quintet,  $J = 6.8$  Hz, 2H), 1.86 (t,  $J = 2.6$  Hz, 1H);  $^{13}\text{C}$  NMR (125 MHz,  $\text{CDCl}_3$ ) ppm 164.8, 160.8,

134.1, 128.2, 113.6, 84.7, 68.4, 55.4, 50.5, 30.0, 16.5, 15.5; HRMS (FAB): Exact mass calcd for  $C_{14}H_{17}NO$   $[M+H]^+$ , 216.1388. Found 216.1389.

**(4S,5S,E)-Ethyl 4-((tert-Butyldimethylsilyl)oxy)-7-hydroxy-5-methylhept-2-enoate (17)**—In a 200 mL round bottom flask charged with  $BH_3 \cdot DMS$  (4.80 mL, 50.6 mmol) at 0 °C was added 2-methyl-2-butene dropwise (11.9 mL, 102 mmol). The colorless mixture was stirred for 15 min, warmed to rt for 1.5 h, then re-cooled to 0 °C. To this mixture, a pre-cooled solution of alkene **16** (12.6 g, 42.1 mmol) in THF (32.4 mL) was added slowly via cannula addition. The reaction was stirred for 4 h at 0 °C, with the last 30 min having minimal ice within the ice/water bath. The ice was recharged and the reaction was quenched by slow dropwise addition via addition funnel of 3 N NaOH (36.2 mL, 1 drop per 3–4 seconds) and then addition of 30%  $H_2O_2$  (25.1 mL) in the same fashion.<sup>69</sup> The reaction was stirred an additional 10 min and then allowed to warm to rt and stirred overnight (at least 10 h). Satd aq  $Na_2S_2O_3$  was added and the aqueous layer was extracted with EtOAc. The combined organic layers were washed with satd aq NaCl, dried, filtered and concentrated to a cloudy white oil. Column chromatography ( $SiO_2$ , 5-10-20-30-45% ethyl acetate in hexanes) provided **17** as a colorless oil (10.5 g, 79%) along with a small amount of **18** as a colorless oil (1–5%). Data for **17**:  $R_f$  = 0.11 (20% EtOAc/hexanes); IR (film) 3442 (br), 2957, 2931, 2858, 1722  $cm^{-1}$ ;  $^1H$  NMR (400 MHz,  $CDCl_3$ )  $\delta$  6.92 (dd,  $J$  = 15.6, 4.9 Hz, 1H), 5.97 (dd,  $J$  = 15.6, 1.5 Hz, 1H), 4.25–4.20 (m, 1H), 4.21 (qd,  $J$  = 7.1, 1.6 Hz, 2H), 3.77–3.69 (m, 1H), 3.66–3.58 (m, 1H), 1.90–1.81 (m, 1H), 1.68 (dtd,  $J$  = 13.9, 7.0, 4.6 Hz, 1H), 1.58 (br s, 1H), 1.44 (ddt,  $J$  = 14.4, 8.4, 6.2 Hz, 1H), 1.30 (t,  $J$  = 7.2 Hz, 3H), 0.95–0.91 (m, 3H), 0.93 (s, 9H), 0.07 (s, 3H), 0.03 (s, 3H);  $^{13}C$  NMR (100 MHz,  $CDCl_3$ ) ppm 166.4, 149.0, 121.2, 75.5, 60.5, 60.3, 36.1, 34.4, 25.8, 18.1, 15.4, 14.2, –4.5, –5.0; HRMS (ESI): Exact mass calcd for  $C_{16}H_{32}O_4SiNa$   $[M+Na]^+$  339.1968, found 339.1951.

**Ethyl 2-((2R,3S,4S)-3-((tert-Butyldimethylsilyl)oxy)-4-methyltetrahydro-2H-pyran-2-yl)acetate (18)**—Data is for the major diastereomer only, ratio of major to minor is 3:1.  $R_f$  = 0.22 (10% EtOAc/hexanes); IR (film) 2957, 2931, 2857, 1740  $cm^{-1}$ ;  $^1H$  NMR (500 MHz,  $CDCl_3$ )  $\delta$  4.15 (q,  $J$  = 7.1 Hz, 2H), 3.83 (ddd,  $J$  = 9.4, 9.4, 3.1 Hz, 1H), 3.65–3.61 (m, 2H), 3.48 (dd,  $J$  = 9.0, 4.9 Hz, 1H), 2.72 (dd,  $J$  = 15.0, 3.1 Hz, 1H), 2.26 (dd,  $J$  = 15.0, 9.7 Hz, 1H), 2.15–2.08 (m, 1H), 1.93–1.85 (m, 1H), 1.48 (ddd,  $J$  = 13.8, 5.1, 2.3 Hz, 1H), 1.25 (t,  $J$  = 7.1 Hz, 3H), 1.05 (d,  $J$  = 7.2 Hz, 3H), 0.88 (s, 9H), 0.05 (s, 6H);  $^{13}C$  NMR (125 MHz,  $CDCl_3$ ) ppm 172.3, 73.4, 73.2, 62.5, 60.6, 38.5, 32.6, 31.9, 36.0, 18.2, 14.4, 11.5, –4.0, –4.8; HRMS (CI): Exact mass calcd for  $C_{16}H_{33}O_4Si$   $[M+H]^+$  317.2143, found 317.2136.

**(3S,4S,E)-4-((tert-Butyldimethylsilyl)oxy)-7-ethoxy-3-methyl-7-oxohept-5-enoic acid (19)**—Aldehyde **76** (9.7 g, 31 mmol) was added to  $CH_3CN$ / $^tBuOH$ /2-methyl-2-butene (3:3:1, 760 mL) and cooled to 0 °C. In an Erlenmeyer flask,  $NaH_2PO_4 \cdot H_2O$  (33.9 g, 245 mmol) was dissolved in  $H_2O$  (210 mL) via stirring and then  $NaClO_2$  (31.3 g, 277 mmol, 80% tech grade) was added in small portions until it was completely dissolved (the solution turns from colorless to yellow). The solution in the Erlenmeyer flask was then poured into a pressure addition funnel and added dropwise to the stirred aldehyde solution. After 1 hr at 0 °C, the reaction was warmed to rt for an additional 2.5 h. Ether was added and the two layers were separated. The organic layer was washed once with satd aq  $Na_2S_2O_3$  and then brine and dried, filtered, and concentrated to a crude oil. Column chromatography ( $SiO_2$ , 10-15-25-40% ethyl acetate in hexanes) provided carboxylic acid **19** as a pale yellow oil (9.1 g, 90% yield).  $R_f$  = 0.10 (20% EtOAc/hexanes);  $[\alpha]_D^{20}$  +1.8 ( $c$  0.8,  $CHCl_3$ ); IR (film) 3100 (br), 2957, 2932, 2858, 1714  $cm^{-1}$ ;  $^1H$  NMR (500 MHz,  $CDCl_3$ )  $\delta$  6.86 (dd,  $J$  = 15.6, 5.1 Hz, 1H), 5.97 (dd,  $J$  = 15.6, 1.4 Hz, 1H), 4.22–4.15 (m, 1H), 4.19 (qd,  $J$  = 7.0, 2.8 Hz, 2H), 2.50–2.43 (m, 1H), 2.20–2.12 (m, 2H), 1.29 (t,  $J$  = 7.1 Hz, 3H), 0.99 (d,  $J$  = 6.2 Hz, 3H), 0.90

(s, 9H), 0.05 (s, 3H), 0.00 (s, 3H), OH hydrogen was not observed;  $^{13}\text{C}$  NMR (125 MHz,  $\text{CDCl}_3$ ) ppm 179.0, 166.2, 148.5, 121.7, 74.7, 60.4, 36.1, 35.9, 25.7, 18.0, 16.2, 14.1, -4.5, -5.1; HRMS (ESI): Exact mass calcd for  $\text{C}_{16}\text{H}_{30}\text{O}_5\text{NaSi}$   $[\text{M}+\text{Na}]^+$  353.1760, found 353.1765.

**(6a*S*,7*S*,8*S*)-7-((*tert*-Butyldimethylsilyl)oxy)-8-methyl-2,3,6a,7,8,9-hexahydropyrrolo[2,1-*a*]isoquinoline-5,10(1*H*,6*H*)-dione (26)**—To a solution of vinylogous amide **6** (280 mg, 530  $\mu\text{mol}$ ) in toluene at 0 °C was added to oil-free NaH (15.3 mg, 640  $\mu\text{mol}$ , oil was removed by washing 3x with hexanes under an inert atmosphere). The reaction was stirred for 3 h at rt and then quenched with water. The mixture was extracted with EtOAc and the organic layers were dried, filtered, and concentrated to a brown oil. Flash column chromatography ( $\text{SiO}_2$ , 50-65-100% ether in hexanes) yielded **26** as a cream-colored, powdery solid (184 mg, 72%); mp 136.5–138.0 °C;  $R_f$  = 0.47 (60% EtOAc/hexanes); IR (film) 2947, 2931, 2886, 2857, 1696, 1669, 1586  $\text{cm}^{-1}$ ;  $^1\text{H}$  NMR (500 MHz,  $\text{CDCl}_3$ )  $\delta$  3.82 (ddd,  $J$  = 11.7, 7.9, 6.1 Hz, 1H), 3.75 (dd,  $J$  = 9.5, 3.7 Hz, 1H), 3.62 (ddd,  $J$  = 11.6, 7.6, 7.6 Hz, 1H), 3.33–3.24 (m, 1H), 3.12 (dddd,  $J$  = 18.2, 8.9, 6.6, 2.6 Hz, 1H), 2.96–2.88 (m, 1H), 2.84 (dd,  $J$  = 16.1, 5.2 Hz, 1H), 2.50 (dd,  $J$  = 17.8, 5.3 Hz, 1H), 2.38 (dd,  $J$  = 17.7, 2.6 Hz, 1H), 2.19–2.11 (m, 2H), 2.06–1.92 (m, 2H), 1.01 (d,  $J$  = 7.1 Hz, 3H), 0.91 (s, 9H), 0.09 (s, 3H), 0.08 (s, 3H);  $^{13}\text{C}$  NMR (125 MHz,  $\text{CDCl}_3$ ) ppm 196.1, 169.5, 155.1, 106.6, 74.9, 45.6, 45.1, 36.0, 35.8, 33.7, 32.0, 25.7, 21.3, 17.9, 12.9, -4.4, -4.8; HRMS (CI): Exact mass calcd for  $\text{C}_{19}\text{H}_{32}\text{NO}_3\text{Si}$   $[\text{M}+\text{H}]^+$  350.2151, found 350.2154; *Anal.* calcd for  $\text{C}_{19}\text{H}_{31}\text{NO}_3\text{Si}$ : C, 65.29; H, 8.94; N, 4.01. **(6a*S*,7*S*,8*S*,10a*R*,10b*R*)-7-((*tert*-Butyldimethylsilyl)oxy)-8-methyloctahydropyrrolo[2,1-*a*]isoquinoline-5,10(6*H*,10a*H*)-dione (31)**—Vinylogous amide **6** (4.0 mg, 10  $\mu\text{mol}$ ) and 10% Pd/C (1.7 mg) in MeOH (200  $\mu\text{L}$ ) were combined in a small vial, placed into a metal chamber, and pressurized to 70 psi with hydrogen. The reaction mixture was stirred for 72 h before it was filtered, concentrated, and purified via flash column chromatography ( $\text{SiO}_2$ , 70-90-100% ethyl acetate in hexanes) to yield ketone **31** as a white, crystalline solid (2.0 mg, 56%) as well as unreacted **6** (1.5 mg, 38%).  $R_f$  = 0.43 (80% EtOAc/hexanes); mp 138.5–139.0 °C; IR (film) 2956, 2930, 2856, 1715, 1642  $\text{cm}^{-1}$ ;  $^1\text{H}$  NMR (400 MHz,  $\text{CDCl}_3$ )  $\delta$  4.12 (ddd,  $J$  = 12.2, 9.7, 6.2 Hz, 1H), 3.87 (dd,  $J$  = 9.2, 4.2 Hz, 1H), 3.63 (ddd,  $J$  = 11.4, 5.5, 5.5 Hz, 1H), 2.96 (ddd,  $J$  = 11.1, 11.1, 5.4 Hz, 1H), 2.79–2.70 (m, 2H), 2.62 (dd,  $J$  = 15.2, 5.1 Hz, 1H), 2.45–2.38 (m, 1H), 2.37 (dd,  $J$  = 15.2, 2.8 Hz, 1H), 2.34–2.26 (m, 1H), 2.18–2.09 (m, 2H), 1.92–1.78 (m, 2H), 1.17 (dddd,  $J$  = 11.7, 11.7, 9.9, 9.9 Hz, 1H), 0.98–0.87 (m, 12H), 0.13 (s, 3H), 0.10 (s, 3H);  $^{13}\text{C}$  NMR (100 MHz,  $\text{CDCl}_3$ ) ppm 206.6, 168.9, 75.0, 57.3, 49.7, 46.3, 42.9, 38.9, 36.2, 34.3, 27.0, 26.0, 21.9, 18.3, 12.9, -4.0, -4.4. HRMS (EI): Exact mass calcd for  $\text{C}_{15}\text{H}_{24}\text{NO}_3\text{Si}$   $[\text{M}-\text{C}_4\text{H}_9]^+$  294.1525, found 294.1530. An x-ray crystal structure of **31** was obtained in which co-crystallization occurred with an  $\alpha$ -hydroxy compound (not shown) as the minor component. See Supporting Information 2 for more details as well as detailed 2D NMR data.

**Alternate Preparation of 31**—Catecholborane (1.14 mL, 1.14 mmol) was added to a solution of vinylogous imide **26** (200 mg, 572  $\mu\text{mol}$ ) and Wilkinson's catalyst (26 mg, 29  $\mu\text{mol}$ ) in THF (2 mL) at 0 °C. The reaction was quenched after 30 min by the addition of MeOH and concentrated to a brown oil. Flash column chromatography ( $\text{SiO}_2$ , 60-80-100% ethyl acetate in hexanes) provided a ketone as a white solid (170 mg, 84%) whose analytical data and  $^1\text{H}$  NMR matched **31**.

**(6a*S*,7*S*,8*S*,10a*S*,10b*R*)-7-((*tert*-Butyldimethylsilyl)oxy)-8-methyloctahydropyrrolo[2,1-*a*]isoquinoline-5,10(6*H*,10a*H*)-dione (32)**—Oil-free NaH (700  $\mu\text{g}$ , 28.4  $\mu\text{mol}$ , oil was removed by washing 3x with hexanes under an inert

atmosphere) was added to a stirred solution of ketone **31** (10.0 mg, 28.4  $\mu\text{mol}$ ) in benzene (280  $\mu\text{L}$ ) and the reaction was heated to 60  $^{\circ}\text{C}$  for 30 min. The reaction was quenched with water and then extracted with EtOAc. The organic layers were dried, filtered, and concentrated to a yellow oil that was purified via flash column chromatography (70–90% ethyl acetate in hexanes) to give ketone epimer **32** as a colorless oil (8.7 mg, 87%).  $R_f$  = 0.20 (80% EtOAc/hexanes); IR (film) 2955, 2928, 2889, 2856, 1715, 1653  $\text{cm}^{-1}$ ;  $^1\text{H}$  NMR (400 MHz,  $\text{CDCl}_3$ )  $\delta$  4.19–4.12 (m, 1H), 3.78–3.69 (m, 2H), 3.40–3.32 (m, 1H), 2.96–2.94 (m, 1H), 2.54 (dd,  $J$  = 13.2, 13.2 Hz, 1H), 2.43 (dddd,  $J$  = 13.3, 6.8, 6.8, 3.4 Hz, 1H), 2.26 (dd,  $J$  = 13.8, 4.4 Hz, 1H), 2.21 (ddd,  $J$  = 15.5, 3.2, 1.4 Hz, 1H), 2.16–2.07 (m, 1H), 2.05–1.96 (m, 2H), 1.93 (dd,  $J$  = 14.3, 13.1 Hz, 1H), 1.90–1.81 (m, 1H), 1.46 (dddd,  $J$  = 11.4, 11.4, 11.4, 8.2 Hz, 1H), 1.04 (d,  $J$  = 6.7 Hz, 3H), 0.95 (s, 9H), 0.13 (s, 3H), 0.12 (s, 3H);  $^{13}\text{C}$  NMR (100 MHz,  $\text{CDCl}_3$ ) ppm 209.4, 168.6, 72.8, 54.2, 47.1, 44.0, 43.7, 41.6, 34.2, 34.2, 32.4, 26.0, 22.1, 18.3, 18.2, –4.2, –4.4; HRMS (CI): Exact mass calcd for  $\text{C}_{19}\text{H}_{34}\text{NO}_3\text{Si}$  [ $\text{M} + \text{H}$ ] $^+$  352.2310, found 352.2308; *Anal.* calcd for  $\text{C}_{19}\text{H}_{33}\text{NO}_3\text{Si}$ : C, 64.91; H, 9.46; N, 3.98. Found: C, 65.01; H, 9.26; N, 3.70. Additional 2D data for **32** can be found in Supporting Information 2.

**Alternate Preparation of 32**— $\text{NH}_3$  (9 mL) was condensed into a two-necked flask at  $-78^{\circ}\text{C}$ . Oil-free lithium wire (9 mg, washed once with hexanes to remove the oil) was added and the reaction was stirred until a blue color persisted for at least 10 min. A solution of vinylogous imide **26** (75.3 mg, 214  $\mu\text{mol}$ ),  $t\text{BuOH}$  (20.5  $\mu\text{L}$ , 214  $\mu\text{mol}$ ), and THF (600  $\mu\text{L}$ ) were added dropwise via dropwise. After 20 min the reaction was quenched by the addition of water and was warmed to rt to evaporate the  $\text{NH}_3$ . The crude reaction was then extracted with EtOAc and the combined organic layers were dried, filtered, and concentrated to a pale yellow oil. Flash column chromatography ( $\text{SiO}_2$ , 70–90–100% ethyl acetate in hexanes) yielded a colorless oil identical in analytical data and matching  $^1\text{H}$  NMR to ketone epimer **32** (47.3 mg, 63%).

**(6aS,7S,8S,10bR)-10-(Allyloxy)-7-((tert-butyldimethylsilyl)oxy)-8-methyl-1,2,3,6a,7,8,9,10b-octahydropyrrolo[2,1-a]isoquinolin-5(6H)-one (33)—**

Ketone **31** (20.0 mg, 56.9  $\mu\text{mol}$ ) was added to a stirred mixture of  $\text{KO}^t\text{Bu}$  (7.0 mg, 63  $\mu\text{mol}$ ) and HMPA (49  $\mu\text{L}$ , 284  $\mu\text{mol}$ ) in  $\text{C}_6\text{H}_6$  (600  $\mu\text{L}$ ) at 0  $^{\circ}\text{C}$ . After 10 min, the reaction was warmed to rt and stirred for an additional 2 h before quenching with satd aq  $\text{NaHCO}_3$ . The mixture was extracted with EtOAc and the combined organic layers were dried, filtered, and concentrated to a brown oil. Flash column chromatography (50–70–100% ethyl acetate in hexanes) yielded **33** as a colorless oil (13 mg, 58%);  $R_f$  = 0.33 (65% EtOAc/hexanes); IR (film) 2956, 2929, 2885, 2856, 1653, 1647, 1457  $\text{cm}^{-1}$ ;  $^1\text{H}$  NMR (400 MHz,  $\text{CDCl}_3$ )  $\delta$  5.91 (dddd,  $J$  = 15.8, 10.5, 5.2, 5.2 Hz, 1H), 5.29 (dd,  $J$  = 17.2, 1.6 Hz, 1H), 5.20 (dd,  $J$  = 10.5, 1.4 Hz, 1H), 4.27–4.22 (m, 3H), 3.70 (ddd,  $J$  = 12.0, 8.7, 8.7 Hz, 1H), 3.43 (dd,  $J$  = 7.6, 3.6 Hz, 1H), 3.35–3.27 (m, 1H), 2.65 (dd,  $J$  = 15.2, 3.7 Hz, 1H), 2.44–2.30 (m, 3H), 2.11–2.07 (m, 1H), 2.04–1.98 (m, 1H), 1.94–1.85 (m, 2H), 1.82–1.78 (m, 1H), 1.36 (dddd,  $J$  = 11.6, 11.6, 11.6, 8.2 Hz, 1H), 0.96 (d,  $J$  = 7.2 Hz, 3H), 0.88 (s, 9H), 0.06 (s, 3H), 0.04 (s, 3H);  $^{13}\text{C}$  NMR (100 MHz,  $\text{CDCl}_3$ ) – led to decomposition in the time needed to acquire the data and did not allow for characterization; HRMS (CI): Exact mass calcd for  $\text{C}_{22}\text{H}_{38}\text{NO}_3\text{Si}$  [ $\text{M} + \text{H}$ ] $^+$  392.2621, found 392.2611.

**(6aS,7S,8S,10aR,10bR)-10a-Allyl-7-((tert-butyldimethylsilyl)oxy)-8-methyloctahydropyrrolo[2,1-a]isoquinoline-5,10(6H,10aH)-dione (34)—A**

solution of freshly prepared allyl vinyl ether **33** (37.0 mg, 94.5  $\mu\text{mol}$ ) in -dichlorobenzene (1.2 mL) was heated at 170  $^{\circ}\text{C}$  in a sealed tube for 3.5 h. The reaction was concentrated and the crude oil was purified by flash column chromatography ( $\text{SiO}_2$ , 40–60% ethyl acetate in hexanes) to give **34** as a colorless oil (29 mg, 78%).  $R_f$  = 0.38 (60% EtOAc/hexanes); IR

(film) 2956, 2929, 2885, 2856, 1653, 1647  $\text{cm}^{-1}$ ;  $^1\text{H}$  NMR (400 MHz,  $\text{CDCl}_3$ )  $\delta$  5.50 (dddd,  $J = 17.1, 10.3, 7.2, 7.2$  Hz, 1H), 5.13 (d,  $J = 9.4$  Hz, 1H), 5.12 (d,  $J = 18.3$  Hz, 1H), 4.16 (ddd,  $J = 12.2, 9.5, 5.6$  Hz, 1H), 4.13-4.07 (m, 1H), 3.42 (dd,  $J = 11.7, 4.9$  Hz, 1H), 2.88 (ddd,  $J = 11.9, 10.3, 6.3$  Hz, 1H), 2.66 (dd,  $J = 14.8, 5.2$  Hz, 1H), 2.70-2.61 (m, 1H), 2.57-2.53 (m, 2H), 2.37-2.27 (m, 4H), 2.25 (dd,  $J = 14.8, 2.4$  Hz, 1H), 1.91-1.75 (m, 2H), 1.27-1.14 (m, 1H), 0.94 (d,  $J = 7.1$  Hz, 3H), 0.91 (s, 9H), 0.12 (s, 3H), 0.09 (s, 3H);  $^1\text{H}$  NMR (400 MHz,  $\text{C}_6\text{D}_6$  - for use with 2D NMR)  $\delta$  5.38 (dddd,  $J = 17.8, 10.0, 7.8, 6.8$  Hz, 1H), 4.95 (d,  $J = 9.5$  Hz, 1H), 4.85 (dd,  $J = 16.8, 1.3$  Hz, 1H), 4.30 (ddd,  $J = 13.1, 9.6, 5.2$  Hz, 1H), 3.78 (dd,  $J = 9.9, 4.8$  Hz, 1H), 3.27 (dd,  $J = 11.6, 4.9$  Hz, 1H), 2.85-2.74 (m, 1H), 2.57 (ddd,  $J = 10.2, 10.2, 6.2$  Hz, 1H), 2.32-2.06 (m, 6H), 1.97 (dd,  $J = 14.8, 2.6$  Hz, 1H), 1.93-1.86 (m, 1H), 1.38-1.15 (m, 2H), 0.95 (s, 9H), 0.80 (d,  $J = 7.1$  Hz, 3H), 0.74-0.62 (m, 1H), 0.04 (s, 3H), 0.03 (s, 3H);  $^{13}\text{C}$  NMR (100 MHz,  $\text{CDCl}_3$ )  $\delta$  ppm 208.9, 169.0, 131.3, 120.4, 71.0, 62.1, 51.8, 45.0, 43.1, 36.6, 36.4, 35.8, 32.8, 26.7, 26.2, 22.2, 18.4, 13.1, -3.9, -4.3; HRMS (EI): Exact mass calcd for  $\text{C}_{22}\text{H}_{38}\text{NO}_3\text{Si}$   $[\text{M}+\text{H}]^+$  392.2621, found 392.2611. 2D NMR data was obtained to support the assignment of the allyl group – see Supporting Information 2 for details.

**(3S,4R,5S,Z)-4-((tert-Butyldimethylsilyl)oxy)-3-(2-hydroxyethyl)-5-methyl-2-(pyrrolidin-2-ylidene)cyclohexanone (35)**—A 1.67 M stock solution of Red-Al (13 mL, 65 wt% in toluene) in toluene (13 mL) was cooled to 0 °C. Of this stock solution, a portion (18.5 mL, 30.9 mmol) was added rapidly to ester **6** (5.10 g, 12.9 mmol) stirring in toluene (103 mL) also at 0 °C.<sup>70</sup> After 30 min, the reaction was warmed to rt and stirred an additional 30 min. It was then cooled to 0 °C before quenching with Rochelle's salt (200 mL) and then warmed again to rt for 20 min. The crude reaction was extracted with EtOAc and the combined organic layers were washed with brine, dried, filtered, and concentrated to a yellow/green oil. Column chromatography ( $\text{SiO}_2$ , 50-70-90% ethyl acetate in hexanes) provided alcohol **35** as a yellow, flaky solid (3.2 g, 70%).  $R_f = 0.18$  (90% EtOAc/hexanes); mp 87.9–89.5 °C; IR (film) 3269 (br), 2953, 2928, 2856, 1603, 1514  $\text{cm}^{-1}$ ;  $^1\text{H}$  NMR (500 MHz,  $\text{CDCl}_3$ )  $\delta$  10.74 (br s, 1H), 3.72 (br s, 1H), 3.69 (t,  $J = 6.3$  Hz, 2H), 3.59 (ddd,  $J = 10.5, 7.8, 6.2$  Hz, 1H), 3.52 (ddd,  $J = 10.4, 7.3, 7.3$  Hz, 1H), 2.72 (ddd,  $J = 16.7, 8.7, 6.5$  Hz, 1H), 2.62-2.58 (m, 1H), 2.57 (ddd,  $J = 16.7, 8.6, 7.1$  Hz, 1H), 2.22 (dd,  $J = 17.5, 12.1$  Hz, 1H), 2.14 (dd,  $J = 17.3, 5.7$  Hz, 1H), 2.13-2.06 (m, 1H), 2.01-1.92 (m, 2H), 1.66-1.52 (m, 3H), 0.95 (d,  $J = 6.5$  Hz, 3H), 0.83 (s, 9H), 0.05 (s, 3H), 0.04 (s, 3H);  $^{13}\text{C}$  NMR (125 MHz,  $\text{CDCl}_3$ ) ppm 194.9, 167.6, 99.9, 73.0, 61.2, 47.6, 41.4, 40.6, 39.5, 30.8, 29.0, 25.9, 21.9, 18.9, 18.3, -4.2, -4.5; HRMS (CI): Exact mass calcd for  $\text{C}_{19}\text{H}_{36}\text{NO}_3\text{Si}$   $[\text{M}+\text{H}]^+$  354.2464, found 354.2454; *Anal.* Calcd for  $\text{C}_{19}\text{H}_{35}\text{NO}_3\text{Si}$ : C, 64.54; H, 9.98; N, 3.96. **(1S,2S,3S,4S,6R,8a'R)-3-((tert-Butyldimethylsilyl)oxy)-2-(2-hydroxyethyl)-4-methylhexahydro-1'H-spiro[cyclohexane-1,8'-indolizin]-6-yl methanesulfonate (63)**

—To a solution of pivalate **58** (42.2 mg, 75.0 μmol) in CH<sub>2</sub>Cl<sub>2</sub>-toluene (1:1, 4.0 mL) at 78 °C was added DIBAL (375 μL, 375 μmol, 1.0 M solution in toluene). The reaction was stirred for 30 min before being warmed to -5 °C and stirred for 5 h. The reaction was quenched with satd aq NH<sub>4</sub>Cl and extracted with CH<sub>2</sub>Cl<sub>2</sub>. The combined organic layers were dried, filtered, and concentrated to a pale yellow oil. Column chromatography (SiO<sub>2</sub>, 10–15% methanol in dichloromethane) provided alcohol **63** as a yellow oil (18.0 mg, 54%).

$R_f$  = 0.11 (10% MeOH/CH<sub>2</sub>Cl<sub>2</sub>);  $[\alpha]_D^{24}$  -32.1 (*c* 0.95, CHCl<sub>3</sub>); IR (film) 3396 (br), 2956, 2928, 2858, 1628 cm<sup>-1</sup>; <sup>1</sup>H NMR (600 MHz, CDCl<sub>3</sub>) δ 4.72 (br d, *J* = 6.0 Hz, 1H), 3.82 (br d, *J* = 10.8 Hz, 1H), 3.70 (s, 1H), 3.65 (dd, *J* = 7.8, 2.4 Hz, 1H), 3.40 (br s, 1H), 3.35–3.31 (m, 1H), 3.06 (s, 3H), 2.79 (br d, *J* = 18.0 Hz, 1H), 2.71 (br s, 1H), 2.60 (br t, *J* = 10.8 Hz, 1H), 2.35–2.28 (m, 2H), 2.22–1.85 (m, 7H), 1.72–1.60 (m, 5H), 0.94 (d, *J* = 6.0 Hz, 3H), 0.91 (s, 9H), 0.88–0.81 (m, 1H), 0.28 (s, 3H), 0.08 (s, 3H); <sup>13</sup>C NMR (150 MHz, CDCl<sub>3</sub>) ppm 82.2, 73.4, 65.2, 60.6, 53.0, 46.8, 42.0, 41.4, 40.8, 31.9, 31.3, 31.2, 30.4, 26.0, 22.7, 19.1, 18.0 (2C), 14.1, -3.9, -5.0; HRMS (EI): Exact mass calcd for C<sub>23</sub>H<sub>46</sub>NO<sub>5</sub>SSi [M+H]<sup>+</sup> 476.2866, found 476.2863.

**(4S,5S,E)-Ethyl 4-((tert-butyldimethylsilyl)oxy)-5-methyl-7-oxohept-2-enoate (S1)**

—Dess-Martin periodinane<sup>72</sup> (30.5 g, 71.9 mmol) was added to alcohol **17** (11.4 g, 36.0 mmol) in CH<sub>2</sub>Cl<sub>2</sub> (200 mL) at rt and stirred for 2 h. By TLC, the reaction was complete and therefore quenched by the addition of an aqueous solution containing 2:1 satd aq Na<sub>2</sub>S<sub>2</sub>O<sub>3</sub>:NaHCO<sub>3</sub> and was stirred until both layers became clear (~20 min). The two layers were separated and the aqueous layer was extracted with CH<sub>2</sub>Cl<sub>2</sub>. The combined organic layers were washed with brine, dried, filtered, and concentrated to a cloudy oil (**S1**), which was pure enough for characterization and could be carried on directly to form **19** (11.0 g, 97%). Data for **S1**:  $R_f$  = 0.40 (20% EtOAc/hexanes);  $[\alpha]_D^{20}$  -5.1 (*c* 0.5, CHCl<sub>3</sub>); IR (film) 2957, 2932, 2887, 1724 cm<sup>-1</sup>; <sup>1</sup>H NMR (500 MHz, CDCl<sub>3</sub>) δ 9.79–9.77 (m, 1H), 6.88 (dd, *J* = 15.6, 5.2 Hz, 1H), 6.00 (dd, *J* = 15.6, 1.6 Hz, 1H), 4.23 (qd, *J* = 7.1, 1.7 Hz, 2H), 4.22–4.19 (m, 1H), 2.57–2.50 (m, 1H), 2.31 (ddd, *J* = 16.1, 8.4, 2.1 Hz, 1H), 2.31–2.24 (m, 1H), 1.33 (t, *J* = 7.1 Hz, 3H), 1.02 (d, *J* = 6.6 Hz, 3H), 0.94 (s, 9H), 0.09 (s, 3H), 0.04 (s, 3H); <sup>13</sup>C NMR (125 MHz, CDCl<sub>3</sub>) ppm 201.9, 166.2, 148.6, 121.8, 75.1, 60.4, 45.8, 34.1, 25.8, 18.1, 16.6, 14.1, -4.4, -5.0; HRMS (CI): Exact mass calcd for C<sub>16</sub>H<sub>30</sub>O<sub>4</sub>NaSi [M+Na]<sup>+</sup> 337.1811, found 337.1798.

19. Using Kakisawa analysis. Ohtani I, Kusumi T, Kashman Y, Kakisawa H. *J Am Chem Soc.* 1991; 113:4092. Full details of the analysis are given in the supporting information and were adapted from: Mutnick, Daniel M. MS Thesis. Indiana UniversityBloomington, IN2003
20. A side product containing a mixture of two diastereomers (**18**) was also observed and was determined to result from conjugate addition of the alkoxide formed during basic workup onto the unsaturated ester. Maintaining the temperature at 0 °C by a slow, dropwise quench during the oxidative work up was necessary to minimize the amount of the undesired cyclization product (**18**).
21. IBX was prepared according to: Frigerio M, Santagostino M, Sputore S. *J Org Chem.* 1999; 64:4537. Dess-Martin was prepared from IBX using (step B only): Boeckman RK, Shao P, Mullins JJ. *Org Syn, Coll.* 2004; 10:696.2000; 77:141.
22. Bal BS, Childers WE Jr, Pinnick HW. *Tetrahedron.* 1981; 37:2091.
23. Continuous extraction of the amine with benzene using a liquid-liquid extractor was utilized due to the high solubility of the amine in water. An alternative workup approach was also successful: After quenching the reaction, the aqueous phase was made basic by addition of excess KOH (5–7 equiv.). The aqueous phase was subsequently extracted with DCM 3 times. The combined organic layers were dried over Na<sub>2</sub>SO<sub>4</sub> and the solvent was evaporated. The crude amine was purified by distillation to provide the product as a light yellow oil.

30. Using *L*-Selectride, a bulky hydride reducing agent, gave the epimer at the pyrrolidine stereocenter (*L*-Selectride, BF<sub>3</sub>·OEt<sub>2</sub>, THF, –78 °C, 48% yield).
31. For chlorination/bromination of vinylogous amides in a similar fashion see: Pierron C, Garnier J, Levy J, LeMen J. *Tetrahedron Lett.* 1971; 12:1007. Jirkovsky I. *Can J Chem.* 1974; 52:55.
32. The α-chloroketone is proposed as an intermediate in the NaOCl oxidation of a vinylogous amide: Staskun B. *J Org Chem.* 1988; 53:5287.
33. While only one diastereomer was formed in each case, the stereocenter of the newly installed functionality could not be confirmed by 2D NOESY measurements as no cross peaks were observed between the cyclohexanone and pyrrolidine rings. The cyclohexanone ring conformation

could be ascertained from 2D NMR measurements and coupling constants. In all schemes, the chair conformation shown is that which was observed on NMR analysis of that compound in solution.

34. For example, see: Molander GA. Chem Rev. 1992; 92:29. Molander GA, Hahn G. J Org Chem. 1986; 51:1135. Enholm EJ, Schreier JA. J Org Chem. 1995; 60:1110.
35. The reaction proceeded cleanly with Fe(acac)<sub>3</sub> present, but resulted in many products without it, see: Molander GA, McKie JA. J Org Chem. 1991; 56:4112.
36. Inanaga J, Ishikawa M, Yamaguchi M. Chem Lett. 1987:1485.

39. This also demonstrates that during the CAN-mediated amine deprotection in the earlier stages of the synthesis, the low yield could also be a result of the vinylogous amide in either the starting material or product being further oxidized with CAN and leading to side products and/or degradation.
40. Evans DA, Allison BD, Yang MG, Masse CE. J Am Chem Soc. 2001; 123:10840. [PubMed: 11686685]

42. Cyclization of the nucleophilic imine was observed any time the primary alcohol was converted to either a leaving group or a carbonyl-containing functional group. This work is described in more detail in reference 26.
43. In their synthesis of (–)-sarain A, Overman et al. reported a similar difficulty in the oxidation of an alcohol proximal to a tertiary amine in the molecule: Garg NK, Hiebert S, Overman LE. Angew Chem Int Ed. 2006; 45:2912.
44. 5-exo cyclizations: Stevens CV, Peristeropoulou M, De Kimpe N. Tetrahedron. 2001; 57:7865. Blough BE, Mascarella SW, Rothman RB, Carroll FI. J Chem Soc Chem Comm. 1993:758. Use of nitrogen-centered imine radical also gives 5-exo cyclization: Callier-Dublanquet AC, Quiclet-Sire B, Zard SZ. Tetrahedron Lett. 1995; 36:8791. 6-endo cyclizations: using a nucleophilic solvent: De Kimpe N, Boelens M, Piqueur J, Baele J. Tetrahedron Lett. 1994; 35:1925. using N-chloroamines: Noack M, Göttlich R. Eur J Org Chem. 2002:3171.
45. a) De Kimpe N, Boelens M, Contreras J. Tetrahedron Lett. 1996; 37:3171. b) Baran PS, Burns NZ. J Am Chem Soc. 2006; 128:3908. [PubMed: 16551088] c) Verhelst SHL, Martinez BP, Timmer MSM, Lodder G, van der Marel GA, Overkleeft HS, van Boom JH. J Org Chem. 2003; 68:9598. [PubMed: 14656083]
46. Both 2D NOESY and HMBC correlations were needed to assign the new structure (*epi*-**49**). The difficult part was in distinguishing the 3 methylene carbons in the 5-membered ring versus the 3 methylene carbons in the 6-membered ring of the indolizidine. The details of the 2D NMR structure elucidation will be published elsewhere.

50. For intramolecular hydroboration of homoallylic and bishomoallylic amine boranes by activation of I<sub>2</sub> at elevated temperatures, see: Scheideman M, Wang G, Vedejs E. J Am Chem Soc. 2008; 130:8669. [PubMed: 18549217] Scheideman M, Shapland P, Vedejs E. J Am Chem Soc. 2003; 125:10502. [PubMed: 12940716] Wang G, Vedejs E. Org Lett. 2009; 11:1059. [PubMed: 19182927]
51. All attempts led to decomposition of the starting material. These include: MeMg, Br; Cossy, J.; Ranaivosata, J-L.; Bellosta, V.; Wietzke, R. Synth Commun. 1995; 25:3109. LiAlH<sub>4</sub> – Yang H-J, Li B-G, Cai X-H, Qi H-Y, Luo Y-G, Zhang G-L. J Nat Prod. 2006; 69:1531. [PubMed: 17125216] Na I, Zn DMF, Lui H-J, Wynn H. Can J Chem. 1986; 64:658.
52. Interestingly, when the  $\alpha$ -alcohol (not protected as the mesylate) was carried through to the piperidinium ring, it still underwent an epimerization of the spirocyclic stereocenter and gave the same product as before (*epi*-**49**) indicating that during the epimerization, the  $\alpha$ -alcohol was also epimerized to the  $\beta$ -alcohol.
53. The one-step Polonovski rearrangement by Kobayashi, which contains the reduction of a similar iminium ion, supports this prediction. See reference 7.

58. Moriarty RM, Zhuang R, Penmasta R, Liu K, Awasthi AK, Tuladhar SM, Singh VK. Tetrahedron Lett. 1993; 34:8029.
59. When  $\beta$ -OH **69** was treated with NaH in DMF, the imine cyclized onto the ester (instead of the  $\beta$ -OH) reforming a similar tricyclic system that was observed before (**26**, *vide infra*) but finally had the allyl group in the correct orientation, which we were not to accomplish previously (see **28** for example). Also,  $\beta$ -OH **69** was recycled using Dess-Martin Periodinane to reform the ketone.
60. The pure tertiary amine was isolated in 53% yield. In addition, an amine:borane complex was isolated as well in 44% yield. This amine borane complex could also be used in the next reaction.

64. Purified according to the procedure in Perrin: Armarego WL, Perrin DD. Purification of Laboratory Chemicals (4). The Bath Press Bath, England 1996
65. An NMR of the  $\beta$ -stannyleneamine was checked. The aryl peaks are integrated to see the ratio of product to starting material, which is usually around 75:25. If the ratio is less than 3:1 (product enamine to starting imine), then the amount of carboxylic acid (**19**) used for the coupling step is decreased so the yield of the coupling reaction is not adversely affected.
66. Veysoglu T, Mitscher LA, Swayze JK. Synthesis. 1980:807.
67. Prepared according to: Li Y, Marks TJ. J Am Chem Soc. 1996; 118:9295.
68. Pickard PL, Tolbert TL. Org Syn, Coll. 1973; 5:520. 1964; 44:51.
69. It was observed that if the NaOH was added too fast (more than 1 drop/3 seconds), then a side product was observed corresponding to intramolecular alkoxide addition to the unsaturated ester (see characterization below for **18**). The H<sub>2</sub>O<sub>2</sub> addition also was monitored carefully due to an exotherm and bubbling. Use of a thermometer inside the reaction during the workup is recommended.
70. To add the Red-Al/toluene rapidly, after pulling the correct amount of stock solution into the syringe, the needle was removed as well as the septum from the reaction flask and the Red-Al was added directly to the reaction in one portion. The 1.67 M stock solution manages to dilute the Red-Al some but it is still a relatively thick solution and best yields were obtained by this method.
71. CH<sub>3</sub>CN was degassed by three cycles of freeze-pump-thaw under high vacuum and back-filling with either argon or nitrogen.

Total Synthesis of 1

**Table 1**

Deprotection and Cyclization Attempts of Vinylogous Amides<sup>a</sup>

entry	vinylogous amide	reagent(s)	result
1	<b>7a</b>	NH <sub>3</sub> CO <sub>2</sub> H, Pd/C	<b>22a</b> <sup>a</sup>
2	<b>7a</b>	HCO <sub>2</sub> H, Pd/C	NR
3	<b>7a</b>	Et <sub>3</sub> SiH, TFA	NR
4	<b>7a</b>	Et <sub>3</sub> SiH, TFA, PhSH	<b>22b</b>
5	<b>7a</b>	EtSH, AlBr <sub>3</sub> (30 equiv)	<b>22b</b>
6	<b>7a</b>	BCl <sub>3</sub>	NR
7	<b>7a</b>	BBr <sub>3</sub>	NR
8	<b>7a</b>	BBr <sub>3</sub> (5 equiv)	<b>22b</b>
9	<b>7a</b>	DDQ	<b>22c</b>
10	<b>7b</b>	DDQ	<b>22c</b>
11	<b>7b</b>	CAN	(PMP) <sub>2</sub> CO <sup>b</sup>
12	<b>7b</b>	DDQ (pH = 7)	<b>22c</b>
13	<b>7b</b>	80% AcOH	<b>22b</b>
14	<b>7b</b>	EtSH, AlBr <sub>3</sub> (30 equiv)	<b>22b</b>
15	<b>7b</b>	KO <sup>t</sup> Bu, DMSO	NR
16	<b>7b</b>	Li, NH <sub>3</sub>	NR
17	<b>7c</b>	KO <sup>t</sup> Bu, DMSO	NR
18	<b>7c</b>	EtSH, AlBr <sub>3</sub> (30 equiv)	<b>22b</b>
19	<b>7c</b>	EtSH, AlBr <sub>3</sub> (0.2 equiv)	NR
20	<b>7c</b>	Li, NH <sub>3</sub>	NR
21	<b>7d</b>	DDQ	<b>22c</b>
22	<b>7d</b>	CAN	<b>6</b>
23	<b>7d</b>	Ph <sub>3</sub> C <sup>+</sup> BF <sub>4</sub> <sup>-</sup>	NR

<sup>a</sup>Deprotection only occurred post reduction of the α,β-unsaturated system, as observed by crude <sup>1</sup>H NMR.

<sup>b</sup>This indicates that the expected ketone from deprotection was isolated. However, the corresponding enamine/cyclized product was not isolated.

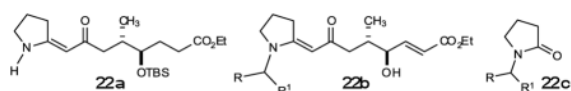

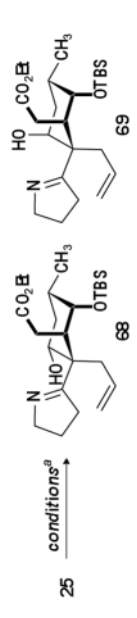

Table 2

## Optimization of Ketone Reduction

entry	reducing agent	solvent	time	$\alpha:\beta$	conversion <sup>b</sup>
1 <sup>c</sup>	NaBH <sub>4</sub>	THF	3 d	>20:1	30–45%
2	NaBH <sub>4</sub>	MeOH	1.5 h	0.8:1	100%
3	NaBH <sub>4</sub>	1-propanol	1.5 h	3:1	100%
4 <sup>c</sup>	LiBH <sub>4</sub>	THF	2 d	>5:1	25%
5	L-Selectride	THF	2 d	---	5%
6 <sup>c</sup>	L-Selectride	MeOH	2 d	4:1	25%
7 <sup>c</sup>	KBH <sub>4</sub>	THF	1 d	4:1	15%

<sup>a</sup> All reactions were performed at  $-3^{\circ}\text{C}$  and employed 1.4 equiv. of reducing agent.

<sup>b</sup> Conversions were measured using  $^1\text{H}$  NMR of the crude reaction mixture.

<sup>c</sup> Decomposition of the starting material was observed.
