A two-dimensional spin field-effect switch

Wenjing Yan^{1,*}, Oihana Txoperena^{1,*}, Roger Llopis¹, Hanan Dery^{2,3}, Luis E. Hueso^{1,4} & Fèlix Casanova^{1,4}

Future development in spintronic devices will require an advanced control of spin currents, for example by an electric field. Here we demonstrate an approach that differs from previous proposals such as the Datta and Das modulator, and that is based on a van de Waals heterostructure of atomically thin graphene and semiconducting MoS₂. Our device combines the superior spin transport properties of graphene with the strong spin-orbit coupling of MoS₂ and allows switching of the spin current in the graphene channel between ON and OFF states by tuning the spin absorption into the MoS₂ with a gate electrode. Our proposal holds potential for technologically relevant applications such as search engines or pattern recognition circuits, and opens possibilities towards electrical injection of spins into transition metal dichalcogenides and alike materials.

he integration of the spin degree of freedom in chargebased electronic devices has revolutionized both sensing and memory capability in microelectronics¹. However, for allowing further development and a successful implementation of spin logic circuits, an electrical manipulation of spin currents is required. The approach followed so far, inspired by the seminal proposal of the Datta and Das spin modulator², has relied on the spin–orbit field as a medium for electrical control of the spin current^{3–6}. However, a challenge is to engineer a material that is capable of transporting spins over long distances and meanwhile has a strong enough spin–orbit coupling (SOC) to allow their electrical manipulation at temperatures above few Kelvin.

For example, carbon-based materials with intrinsic weak SOC, such as organic semiconductors⁷, carbon nanotubes⁸ and graphene⁹, have made a notable impact in spintronics. In particular, graphene has been proved to be ideal for long-distance spin transport (in excess of several micrometres)^{10–15}. However, owing to its weak SOC, spin manipulation in this material has been mainly achieved by an external magnetic field through Hanle precession^{10,13,14}. Although various approaches have been taken to enhance the SOC of graphene, for example through proximity effect^{16–18} or by atomic doping¹⁹, a direct evidence on the modulation of spin transport by an electric field remains elusive.

Meanwhile, transition metal dichalcogenides (TMDs) have emerged to complement graphene due to their unique optical, spin and valley properties^{20,21}. Specifically, MoS₂, the best-known member of that class, has a crossover from an indirect to a direct-gap semiconductor when thinned down to a monolayer (ML)²². Its electronic properties can be strongly modulated by gate, large current ON/OFF ratio as much as 1×10^8 in ML and 1×10^6 in multilayers have been found^{23,24}. Its stronger SOC compared with that of graphene, arising from the *d*-orbitals of the transition metal atoms, offers new possibilities to employ the spin and valley degrees of freedom in TMDs^{20,25–27}.

In our work, the combination of graphene with MoS_2 in a heterostructure through weak van der Waals (vdW) forces²⁸

allows us to engineer an alternative type of field-effect switch for spin transport. A spin current in the graphene section of the device is electrically injected from a ferromagnetic source terminal. The gate electrode controls how much of that spin current is absorbed by the intersecting MoS_2 layer (spin sink) before its arrival to the ferromagnetic drain terminal. By tuning the gate voltage, we were able to switch the spin current between binary ON and OFF states at temperatures up to 200 K. The current device could be scalable and operative at room temperature, considering both the rapid progress made in chemical vapour deposition of two-dimensional (2D) materials and the theoretical performance of the materials involved.

Results

Device structure and measurement configurations. A sketch of the 2D vdW heterostructure and the electrical measurement scheme is shown in Fig. 1a, whereas a scanning electron microscope image of the device is shown in Fig. 1b. Graphene flakes are exfoliated onto a highly doped Si substrate covered by 300 nm of SiO₂. An ML graphene flake is identified according to its optical contrast²⁹ and, subsequently, a few-layer MoS₂ flake is transferred above it by all-dry viscoelastic stamping³⁰. Several Co/TiO₂ electrodes are patterned by electron-beam lithography and evaporated onto the graphene channel, to create lateral spin valves (LSVs; see Methods), which enable the injection and detection of pure spin currents in graphene in a non-local geometry^{10,14}. The non-local resistance $R_{nl} = V_{nl}/I$, which depends on the relative orientation of the magnetisation of the injecting and detecting Co electrodes, is measured while sweeping the magnetic field **B** in-plane along the easy axis of the electrodes (see Fig. 1a for a sketch of the experimental geometry). Specifically, when the configuration of the magnetizations changes from parallel to antiparallel, R_{nl} switches from high (R_p) to low (R_{ap}) value. The spin signal is proportional to the amount of spin current reaching the detector, measured by $\Delta R_{\rm nl} = R_{\rm p} - \bar{R}_{\rm ap}$ (Fig. 1c).

Figure 1 | Illustration of the experiment and scanning electron microscope (SEM) image of the device. (a) Sketch of the 2D vdW heterostructure to be used for switching the spin transport. For the non-local measurement, a DC current (10 μ A) is injected into graphene from a ferromagnetic Co electrode across a TiO₂ barrier and a non-local voltage (V_{nl}) is measured by a second Co electrode while sweeping the magnetic field B. The red- and blue-coloured circuit diagrams represent the measurement configurations in the reference graphene LSV (without MoS₂ on top) and the graphene/MoS₂ LSV (with MoS₂ intercepting the spin current path). In the latter case, the spin current flowing in the graphene can be switched ON and OFF by modulating the conductivity of MoS₂ using an electric field across a SiO₂ dielectric (also shown in the diagram). (b) False-coloured SEM image of the LSV devices. The width of the graphene and MoS₂ are $w_{Gr} = 3 \,\mu$ m and $w_{MoS_2} = 0.4 \,\mu$ m, respectively. Scale bar, 2 μ m. (c) An illustration of a typical non-local magnetoresistance measurement, where the non-local resistance R_{nl} switches between R_P and R_{AP} for parallel and antiparallel magnetization orientations of the Co electrodes. The spin signal is tagged as $\Delta R_{nl} = R_p - R_{ap}$.

Figure 2 | Spin transport in a reference graphene lateral spin valve. Measurements are done using the red-coloured circuit diagram in Fig. 1a. (a) Non-local resistance R_{nl} as a function of the magnetic field **B** measured at different V_g at 50 K. The current bias is 10 µA and the centre-to-centre distance between ferromagnetic electrodes (*L*) is 1 µm. Individual sweeps are offset in R_{nl} for clarity. (**b**) Spin signal ΔR_{nl} measured at different V_g (red circles). The black solid line shows the sheet conductivity of the graphene as a function of V_g . The inset shows schematically the spin current (green arrow) reaching the detector in the full range of V_g . Error bars are calculated using the s.e. associated with the statistical average of the non-local resistance in the parallel and antiparallel states.

Spin transport in a reference graphene lateral spin valve. We first study the spin transport in a graphene LSV without MoS_2 (reference LSV). Figure 2a shows the measured R_{nl} as a function of **B** for different gate voltages (V_g) . On application of V_g , the magnitude of the spin signal weakly varies, following the modification of the graphene sheet conductivity (σ_{Gr}^{\bullet}) with V_g , as can be observed in Fig. 2b. The correlation between ΔR_{nl} and σ_{Gr}^{\bullet} is a signature of a transparent interface between the Co/TiO₂ electrodes and the graphene (~ 250 Ω), as it is well established in the literature¹⁴.

Spin transport in a graphene/MoS₂ spin field-effect switch. Next, we introduce the central results of our manuscript: the demonstration of spin switching by a gate voltage in a graphene/ MoS_2 LSV. Figure 3a shows R_{nl} of this device, while sweeping **B** for different values of $V_{\rm g}$, where a gradual decrease of the spin signal $\Delta R_{\rm nl}$ with $V_{\rm g}$ can be observed. This behaviour is clearly seen in Fig. 3b, where ΔR_{nl} is plotted as a function of V_{g} , showing the decay of $\Delta R_{\rm nl}$ towards zero at positive values of $V_{\rm g}$, in contrast with the weakly varying spin signal measured in the reference LSV (see Fig. 2b). Figure 3b also plots the MoS₂ sheet conductivity ($\sigma_{MoS_2}^{\bullet}$) from a reference device revealing an opposite gate voltage dependence to that of $\Delta R_{\rm nl}$. For large negative $V_{\rm g}$, the semiconducting MoS₂ is in the low conductivity OFF state and the measured ΔR_{nl} value is comparable to that of the reference LSV, reaching the ON state of the device. This result is expected, considering that the electrode spacing here is slightly longer than in the reference LSV (1.8 versus 1 µm; see Fig. 1b for comparison). Sweeping the gate voltage towards positive values brings the MoS₂ towards its high conductivity ON state, where $\sigma_{MoS_2}^{\blacksquare}$ increases by more than six orders of magnitude compared with the OFF state. Simultaneously, the spin current reaching the detector and the corresponding ΔR_{nl} gradually decrease towards zero (see Fig. 3b), reaching the OFF state of the device for $V_{\rm g}$ >15 V. The change in spin signal per gate voltage unit in our device is ~0.7 m Ω V⁻¹. The results are completely reproducible upon multiple gate voltage sweeps and temperature cycles, evidencing the robustness of the effect (Supplementary Fig. 1). Similar results to those in Fig. 3b are also observed at temperatures up to 200 K (Supplementary Fig. 2).

This control of the spin current directly demonstrates the 2D spin field-effect switch. This proof-of-principle effect can be enhanced by using a different dielectric, for example, layered hexagonal BN^{24,31}, or by tuning the interface resistance between graphene and Co¹⁴.

Discussion

The switching of spin transport using the graphene/MoS₂ vdW heterostructure relies on the absorption of spins travelling through the graphene by the MoS₂, as schematically illustrated in the inset of Fig. 3b. To support this argument, we make use of the spin resistances of the channel (graphene) and the absorbing material (MoS₂), which are the main control parameters in the spin absorption mechanism. Roughly, they can quantify how easily the spin current flows through each of the materials, in the same way in which one can estimate a charge current flow in parallel electrical resistors. The spin resistances of graphene and MoS₂ can be expressed as $R_{Gr}^{S} = \frac{R_{Gr}^{\bullet} \lambda_{Gr}}{w_{Gr}}$ and $R_{MoS_2}^{S} = \frac{R_{MoS_2}^{\bullet} (\lambda_{MoS_2})^2}{w_{Gr} w_{MoS_2}}$, respectively (Supplementary Note 2); where $R_{Gr,MoS_2}^{\bullet} = 1/\sigma_{Gr,MoS_2}^{\bullet}$ are their sheet resistances, λ_{Gr, MoS_2} their spin diffusion lengths and $w_{\text{Gr, MoS}}$, their widths ($w_{\text{Gr}} = 3 \,\mu\text{m}$ and $w_{\text{MoS}} = 0.4 \,\mu\text{m}$). We have estimated the intrinsic spin lifetime in bulk MoS₂ to be in the range of 10 ps (see Supplementary Note 2). For this estimation, we have considered electron interaction with flexural phonons and found weak temperature dependence of the spin relaxation in accord with our experimental results and in contrast to the findings in ML MoS_2 (ref. 27). The lack of space inversion symmetry in a ML has two effects on the spin transport. The first one is to increase the amplitude of the spin-flip matrix element 26 . The second effect is to induce spin splitting of the energy bands at the K point. Although the former effect enhances spin relaxation, the latter one suppresses it when the spin splitting is large enough to exclude elastic scattering. In p-type ML TMDs, for example, the spin splitting in the valence band is of the order of hundreds of meV and the overall spin lifetime is prolonged compared with bulk. In this view, the spin degeneracy of the energy bands in few-layer TMDs renders these materials ideal spin sinks when put in proximity to graphene. Using the estimated spin lifetime in bulk MoS2, we calculate $\lambda_{MoS_2} \sim 20\,\text{nm}$ in the OFF state of the device at $V_{\rm g} = 40$ V. In contrast, the spin diffusion length in graphene is much longer, being $\lambda_{Gr} \sim 1.2\,\mu m$ estimated from Hanle measurements on a reference device (Supplementary Fig. 3). Substituting the spin diffusion lengths, the electrical properties and geometrical factors of graphene and MoS₂, we obtain $R_{Gr}^{S} = 408 \Omega$ and $R_{MoS_{2}}^{S} = 2.7 \Omega$ $V_{g} = 40 V$ (Supplementary Note 2). The fact that $R_{MoS_{2}}^{S} < < R_{Gr}^{S}$ demonstrates the capability of the MoS₂ to absorb spins from the graphene channel. This is further supported by the low graphene/MoS₂ barrier height at high positive $V_{\rm g}$ (ref. 32), making the interface resistance sufficiently low for efficient spin absorption.

Figure 3 | Spin transport in a graphene/MoS₂ lateral spin valve. Measurements are done using the blue-coloured circuit diagram in Fig. 1a. (a) Non-local resistance R_{nl} measured as a function of the magnetic field **B** at different V_g at 50 K using 10 µA current bias and for a centre-to-centre distance between ferromagnetic electrodes (*L*) of 1.8 µm. Individual sweeps are offset in R_{nl} for clarity. (**b**) Gate modulation of the spin signal ΔR_{nl} (blue circles). The black solid line is the sheet conductivity of the MoS₂ as a function of V_g . The insets show schematically the spin current path (green arrow) in the OFF state (left inset) and the ON state (right inset) of MoS₂. Error bars are calculated using the s.e. associated with the statistical average of the nonlocal resistance in the parallel and antiparallel states.

The situation completely changes when the gate voltage V_g is swept towards negative values. At $V_g = -30$ V, the MoS₂ conductivity $\sigma_{MoS_2}^{\bullet}$ decreases by more than six orders of magnitude from $V_g = 40$ V, which leads to a similar increase in $R_{MoS_2}^S$. Therefore, we have $R_{MoS_2}^S > R_{Gr}^S$, preventing spin absorption by MoS₂. Although the very large spin resistance of MoS₂ alone is sufficient to support the vanishing spin absorption, we note that the interface resistance between graphene and MoS₂ also increases³², further preventing probable spin absorption into the MoS₂. Therefore, the gate dependence of the graphene/MoS₂ interface resistance acts as a positive feedback, further improving the performance in the regime between the fully ON and OFF state of the device.

The inverse correlation between the spin signal ΔR_{nl} and the MoS₂ conductivity $\sigma_{MoS_2}^{\bullet}$ can be clearly seen in Fig. 3b. This correlation supports the aforementioned argument and discards other scenarios, such as spin dephasing in possible trap states at the graphene/MoS₂ interface. The fact that similar results to those in Fig. 3b are also observed at 200 K indicates that the effect barely changes with temperature and therefore is incompatible with the exponential temperature dependence expected for capture and escape in trap states (Supplementary Note 1). Next, we confirm the spin absorption mechanism by computing the expected spin signal ratio, $\Delta R_{nl}^{abs}/\Delta R_{nl}$, which quantifies the relative amount of spins deviating from the graphene channel towards the MoS₂ (ref. 33):

$$\begin{aligned} \frac{\Delta R_{nl}^{abs}}{\Delta R_{nl}} &= \\ \frac{2R_{MoS_2}^{S}\left\{\sinh(L/\lambda_{Gr}) + 2Q_{I}e^{L/\lambda_{Gr}} + 2Q_{I}^{2}e^{L/\lambda_{Gr}}\right\}}{R_{Gr}^{S}\left\{\cosh(L/\lambda_{Gr}) - 1\right\} + 2R_{MoS_2}^{S}\sinh(L/\lambda_{Gr}) + 2R_{I}^{S}\left\{e^{L/\lambda_{Gr}}(1+Q_{I})(1+2Q_{MoS_2}) - 1\right\}}, \end{aligned}$$
(1)

where ΔR_{nl}^{abs} and ΔR_{nl} are the spin signals with and without spin absorption by the MoS₂; $R_{I}^{S} = R_{I}/(1-P_{I}^{2})$ is the spin resistance of the Co/TiO₂/graphene interface, R_{I} is the interface resistance and P_{I} is the interface spin polarisation; and finally, $Q_{MoS_{2}} = \frac{R_{MoS_{2}}^{S}}{R_{Gr}^{S}}$ and $Q_{I} = \frac{R_{I}^{S}}{R_{Gr}^{S}}$. Assuming the interface is transparent at 40 V, one can calculate the expected spin signal ratio when the MoS₂ is fully ON. Substituting the known parameters into equation (1), one gets $\Delta R_{nl}^{abs}/\Delta R_{nl} \approx 0.017$ at $V_{g} = 40$ V (Supplementary Note 3). The very small value calculated for $\Delta R_{nl}^{abs}/\Delta R_{nl}$ predicts a strong spin absorption, which confirms this scenario to be responsible for the observed experimental results of Fig. 3b.

Compared with previous Datta and Das-like spin modulators³⁻⁶, the electrical manipulation of spin transport in our 2D spin fieldeffect switch is observed at much higher temperature (up to 200 K versus few or sub K). It also displays well-defined ON and OFF states, which are easily controlled by the gate electric field instead of an oscillatory spin signal. Moreover, there is plenty of room for the optimization of the device performance. For instance, by incorporating tunnel barriers with higher resistance, the spin signal and thus the difference between the ON and OFF states could be increased by two orders of magnitude³⁴⁻³⁶. The threshold voltage required to turn ON and OFF the device can be reduced by replacing SiO₂ with a thinner dielectric of larger dielectric constant, such as HfO2 (ref. 37) or hexagonal BN24,31. With the above improvements to the fabrication process, and considering the robust performance of MoS₂ transistors at room temperature^{23,24}, a room-temperature 2D spin field-effect switch is envisioned. The recent advances in chemical growth of high quality 2D layered materials^{21,38} and their heterostructure multilayers³⁹⁻⁴¹, as well as in homostructural⁴², and heterostructural³⁶ tunnel barriers for spin injection, may well lead to large-scale integration of the current device architecture. Aside from the potential technological applications, the spin absorption effect in our experiments provides a solution to electrically inject spins into 2D semiconducting TMDs, which has so far been elusive due to the conductivity mismatch problem⁴³⁻⁴⁵

In conclusion, the seamless integration of two 2D layered materials with remarkably different spin–orbit coupling amplitudes leads to a device capable of both transporting and electrically controlling a spin current. The demonstrated 2D spin field-effect switch can improve the performance of search engines or pattern recognition circuits, wherein a large number of independent logic operations are executed in parallel^{15,46,47}. Furthermore, the vdW heterostructure at the core of our experiments opens the path for fundamental research of exotic transport properties predicted for TMDs^{20,25,26}.

Methods

Device fabrication. Fabrication of ML graphene samples uses the mechanical exfoliation method initiated in ref. 29. We first exfoliate bulk graphitic crystals onto a Nitto tape (Nitto SPV 224P) and repeat the cleavage process between three and

five times until thin flakes can be identified visually by the eye. The Nitto tape with relatively thin flakes is pressed against a preheated Si substrate with 300 nm SiO₂. After peeling off the Nitto tape, the substrate is examined under an optical microscope and ML graphene is identified by well-established optical contrast. We then prepare the MoS₂/poly-dimethyl siloxane stamp following ref. 30. First, a MoS₂ crystal is exfoliated twice using the Nitto tape and transferred on to a piece of poly-dimethyl siloxane (Gelpak PF GEL film WF \times 4, 17 mil.). After identifying the desired few-layer MoS₂ flake using optical contrast, it is transferred on top of graphene after slowly removing the viscoelastic stamp.

The lateral spin valve is formed following a standard nanofabrication procedure including electron-beam lithography, metal deposition and metal lift-off in acetone. 5 Å of Ti are deposited by electron-beam evaporation and left to oxidize in air for 0.5 h before depositing 35 nm of Co using electron-beam evaporation.

Electrical measurements. The measurements are performed in a Physical Property Measurement System by Quantum Design, using a 'DC reversal' technique with a Keithley 2182 nanovoltmeter and a 6221 current source. A current bias of 10 μ A is used unless stated in the text. Gate voltage is applied using a Keithley model 2636. The gate voltage is applied between the back of the doped Si substrate and the grounding electrode. As graphene layer on the bottom is ML, it does not fully screen the gate electric field. Therefore, the gate voltage modulates the charge carrier density in both graphene and the MoS₂.

Data availability. All relevant data are available from the authors.

Acknowledgements

The work at CIC nanoGUNE was supported by the European Union 7th Framework Programme under the Marie Curie Actions (607904-13-SPINOGRAPH) and the European Research Council (257654-SPINTROS), by the Spanish MINECO under Project Number MAT2015-65159-R and by the Basque Government under Project Number PC2015-1-01. The work at the University of Rochester was supported by the Department of Energy under Contract Number DE-SC0014349, National Science Foundation under Contract Number DMR-1503601 and the Defense Threat Reduction Agency under Contract Number HDTRA1-13-1-0013.

Author contributions

F.C. conceived the study. W.Y., O.T. and R.L. performed the experiments. W.Y. O.T., L.E.H. and F.C. and analysed the data, discussed the experiments and wrote the manuscript. H.D. performed theoretical calculations on the spin relaxation properties of MoS_2 . All the authors contributed to the scientific discussion and manuscript revision. L.E.H. and F.C. co-supervised the work.
