

The Structure of L-Mimosine, an L-DOPA Analogue

ARVID MOSTAD,^a CHRISTIAN RØMMING^a and
EINAR ROSENQVIST^b

^a Department of Chemistry and ^b Institute of Pharmacy, University of Oslo,
Oslo 3, Norway

The crystal structure of L-mimosine, β -N-(3-hydroxy-4-pyridone)- α -amino propionic acid, has been determined by X-ray methods using 1729 observed reflections collected by counter methods. The crystals are orthorhombic, space group $P2_{1}2_{1}2_{1}$, with unit cell dimensions $a = 20.45$ Å; $b = 9.48$ Å; $c = 8.50$ Å. The asymmetric unit consists of two independent molecules. The refinements yielded a conventional R -factor of 0.064; estimated standard deviations are about 0.005 Å in bond lengths and 0.3° in angles. The conformation of the two non-equivalent molecules is nearly identical and is similar to that found in L-DOPA. The pyridone ring has a pronounced quinoid character.

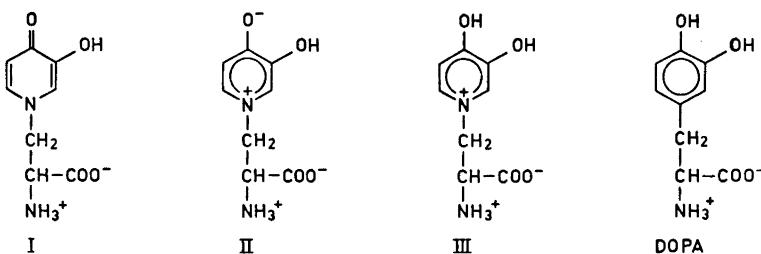

Mimosine, β -N-(3-hydroxy-4-pyridone)- α -amino propionic acid, leucenol, is a naturally occurring amino acid found in certain plants.¹ Its notable biological properties have been described by several authors and summarized by Owen.² Hegarthy *et al.*³ point out that inhibition of mitosis in the hair follicle is the reason for hair loss in sheep by mimosine intoxication, Hylin and Lichten⁴ report the loss of fertility in female rats by ingestion of mimosine, and Prabhakaran *et al.*⁵ found that injection of the compound inhibit the development of melanoma in mice.

Thompson *et al.*¹ have reviewed various theories for the mechanisms of the toxic action of mimosine in animals. One of these depends on the structural similarity between mimosine and DOPA; mimosine may thus interact with the enzymes concerned with the DOPA metabolism.

The chemical formula for mimosine is usually written as I. Several authors⁶⁻⁸ have, however, indicated II as an important contributor to the electronic structure. It may be seen that III, the protonized form of II, is isoelectronic with DOPA.

The absolute configuration of L-mimosine has been investigated by chemical methods⁹ and shown to belong to the S-series.

After the publication of the X-ray structure analysis of L-DOPA,¹⁰ Dr. Hegarthy pointed out for us the analogy between this compound and mimosine and suggested a structure analysis of the latter compound; he also kindly supplied a sample of pure L-mimosine.

EXPERIMENTAL

A hot saturated solution of L-mimosine was cooled to room temperature during a period of 2–3 days. Single crystals in the form of thin, needle-formed very brittle plates separated; a crystal roughly cut to the dimensions $0.13 \times 0.21 \times 0.06$ mm³ was used for the X-ray experiments.

Oscillation and Weissenberg photographs indicated orthorhombic symmetry; systematically absent reflections determined the space group to be $P2_12_12_1$.

Unit cell parameters were determined from diffractometer measurements on 62 reflections using a manual Picker diffractometer with a copper tube ($\lambda_{\beta} = 1.3922$ Å, $\lambda_{\alpha_1} + \lambda_{\alpha_2} = 1.5418$ Å). The take-off angle was 1.0°. The computer program employed in the least-squares calculation of cell parameters as well as the programs applied during the structure investigation are described in Ref. 11.

Three-dimensional intensity data were recorded on an automatic Picker four-angle diffractometer using graphite crystal monochromated MoK radiation. The take-off angle was 4°. Intensities of 2640 reflections with $2\theta < 60^\circ$ were measured using the $\omega - 2\theta$ scanning mode with a 2θ scanning speed of 1° min⁻¹. Background counts were taken for 20 sec at each of the scan range limits. Three standard reflections measured after every 100 reflections showed a variation of up to 10% during the run; the intensity data were accordingly adjusted. Estimated standard deviations in the intensities were taken as the square root of the total counts with a 2.5% addition to allow for the uncertainty in the adjustments.

The 1729 reflections with intensity larger than 2σ (I) were considered to be observed; the rest were regarded as unobserved and excluded from the refinement procedure. Lorentz and polarization corrections were applied to the intensity data.

Atomic form factors used were those of Hanson *et al.*¹² for oxygen, nitrogen, and carbon, and of Stewart *et al.*¹³ for hydrogen.

CRYSTAL DATA

S-β-N-(3-hydroxy-4-pyridone)-α-amino propionic acid (L-mimosine, leucenol), $C_8H_{10}N_2O_4$, orthorhombic. $a = 20.453(0.002)$ Å, $b = 9.485(0.001)$ Å; $c = 8.500(0.001)$ Å. Figures in parentheses are estimated standard deviations. $V = 1648.9$ Å³; $M = 198.18$; $F(000) = 832$; $Z = 8$; $D_{\text{obs}} = 1.59$ g cm⁻³ (flotation); $D_{\text{calc}} = 1.595$ g cm⁻³. Absent reflections: $(h00)$ for h odd, $(0k0)$ for k odd, $(00l)$ for l odd; space group $P2_12_12_1$.

STRUCTURE DETERMINATION

The data were put on an absolute scale by Wilson's statistical method and normalized structure amplitudes were calculated. Eight sets of phases for 250 structure amplitudes were obtained by the application of the symbolic

Table 2. Fractional atomic coordinates and thermal parameters with estimated standard deviations ($\times 10^6$). The temperature factor is given by $\exp - (B_{11}h^2 + B_{22}k^2 + B_{33}l^2 + B_{12}hk + B_{13}hl + B_{23}kl)$.

DISCUSSION

A drawing of the two molecules (I and II) in the asymmetric unit is presented in Fig. 1; the numbering of the atoms is indicated, as are the bond lengths and angles arrived at in the structure analysis. Interatomic distances and bond angles are also given in Table 4 together with their standard deviations. The latter values might be somewhat underestimated, however, since possible correlations between positional parameters of different atoms are disregarded in the computing procedure.

The crystals of L-mimosine offer the opportunity to study two non-equivalent molecules in different environment. However, the different surroundings seem to have only minor influence on the molecular structure as the bond lengths and angles as well as the conformation of the two molecules are nearly equal.

The molecular conformation. Both of the molecules in the asymmetric unit have a conformation similar to the one found in L-DOPA.¹⁰ The dihedral angle C1—N—C6—C7 is 275° and C1*N*—C6*—C7* 113°, the side chain is thus situated on opposite sides of the ring plane in the two molecules, and the molecule II (*) is the one corresponding to L-DOPA.

The carboxyl groups are in *trans* position relative to the phenyl rings with respect to the C α —C β bond; the dihedral angles N—C6—C7—C8 and N*—C6*—C7*—C8* are 172° and 178°, respectively, as compared to 175° for the corresponding angle in L-DOPA.

The alanine part. The zwitterionic character of the molecule is apparent in the present structure as usual for such compounds. The four C—O bonds of the carboxy groups are equal, mean bond length 1.242 Å, with a calculated standard deviation equal to the estimated standard deviation of each bond, 0.005 Å. The C—NH₃⁺ bonds, 1.472 and 1.484 Å, are possibly on the short side of the expected value 1.49 Å, as found in L-DOPA¹⁰ and L-tyrosine.¹⁷ The C6—C7 bonds (1.530 and 1.515) are found to be slightly shorter than the C7—C8 bonds (1.552 and 1.550 Å). The α carbon atom is within the experimental accuracy situated in the plane of the carboxy group in both molecules. The dihedral angle N2—C7—C8—O4 is 350.1° (in clock-wise direction) and the N2*—C7*—C8*—O4* angle is 334.8° (e.s.d. 0.5°), both being within the limits

Table 4. Interatomic distances (\AA) and bond angles ($^\circ$). Estimated standard deviations are 0.005 \AA and 0.3° , respectively.

reported for amino acids.¹⁸ In both molecules the hydrogen atoms are tetrahedrally arranged about the nitrogen atom; their positions correspond to a $10-15^\circ$ rotation about the C—N bond relative to a strictly staggered conformation.

The hydroxypyridone part. The six-membered rings are nearly planar, the deviations of the atoms from a least-squares plane being less than 0.03 \AA . The non-hydrogen atoms attached to the rings are situated from 0.05 to 0.12 \AA out of the ring planes.

Except for the C3—O1 and the C3*—O1* bond lengths the two hydroxypyridone moieties are identical. An estimate of the relative contribution to the structure from the formulae I and II indicated in the introduction may be based on several features in the geometry. The mean value of the C1—C2, C4—C5, C1*—C2*, and the C4*—C5* bonds is 1.361 \AA (e.s.d. 0.005 \AA) as compared to the mean value for C2—C3, C3—C4, C2*—C3* and C3*—C4* of 1.419 \AA (e.s.d. 0.007 \AA). The corresponding bond lengths in quinone are 1.322 \AA and 1.477 \AA ,¹⁹ and in quinone in the quinone-resorcinol complex 1.330 \AA and 1.468 \AA ,²⁰ respectively. The C—C bond length to be expected for

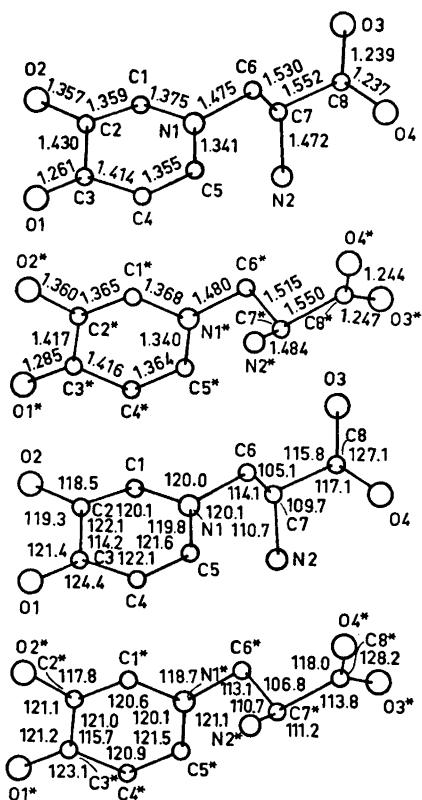

Fig. 1. Bond lengths (\AA) and angles ($^{\circ}$) observed in L-mimosine.

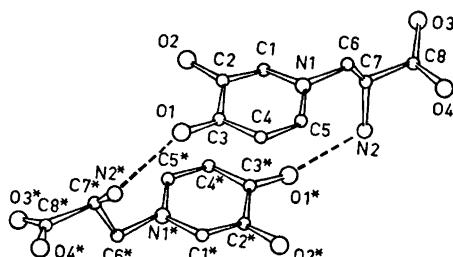

Fig. 2. The dimeric arrangement of the two crystallographically independent molecules of L-mimosine.

an aromatic model is 1.397 \AA ; the contributions from the two extreme structures appear thus to be about equal. This feature is also indicated by the C3—O1 and C3*—O1* bonds of 1.261 \AA and 1.285 \AA , these being close to the mean length of the quinone C=O bond (1.22 \AA) and the phenolic C—O bond (1.36–1.38 \AA).

From these results one might expect the C—N bond lengths to be somewhere between the values reported for pyrrol, 1.374²¹ ("quinoid" case) and for pyridine, 1.339²² ("aromatic" case). In the present structure determination both of these values were found for the C—N bonds, the C1—N1 bond being the longer in both molecules. The difference between the two C—N bonds in each of the two independent molecules is significant according to normal standards of structure analysis; we find no obvious explanation for this difference, however.

The two phenolic C—O bonds are equal in the two molecules, 1.357 and 1.360 \AA , respectively.

The bond between the hydroxypyridone and the alanine moieties, N1–C6, is found equal to 1.475 and 1.480 Å. The N_{sp^2} – C_{sp^3} bond length to be expected is somewhat shorter than the aliphatic N–C of 1.47 Å; the relative lengthening in the present case may be attributed to the positive charge on the nitrogen atom in analogy with the bond length in C_{sp^2} – NH_3^+ of 1.49 Å.

The crystal structure. Packing and hydrogen bonding. The high values for the melting point (decomp. 227–228°C) and density (1.59 g cm⁻³) indicate strong intermolecular forces and a close packing of the molecules in the crystal. The packing coefficient²³ estimated from data given by Bondi²⁴ is as high as 0.82 as compared with the one calculated for L-DOPA of 0.79 and L-tyrosine of 0.75, whereas a normal value for benzene derivatives is given by Kitaygorodskii²³ to be 0.69. It seems reasonable to relate the high values to the zwitterionic character of the molecules, especially for L-mimosine. From the partial quinoid structure it may be deduced that the nitrogen atom in the ring is positively and the keto oxygen atom negatively charged. This also seems reasonable from the way pairs of crystallographically independent molecules are forming dimers in the crystals. The asymmetric unit may be represented as visualized in Fig. 2. The two molecules are linked together by two hydrogen bonds, O1–N2* (2.699 Å) and O1*–N2 (2.872 Å). The planes of the pyridone moieties are nearly parallel, the interplanar separation being 3.4 Å. The shortest distances between atoms from each molecule apart from the hydrogen bonded atoms are N1–O1* of 3.448 Å and N1*–O1 of 3.348 Å. This may indicate

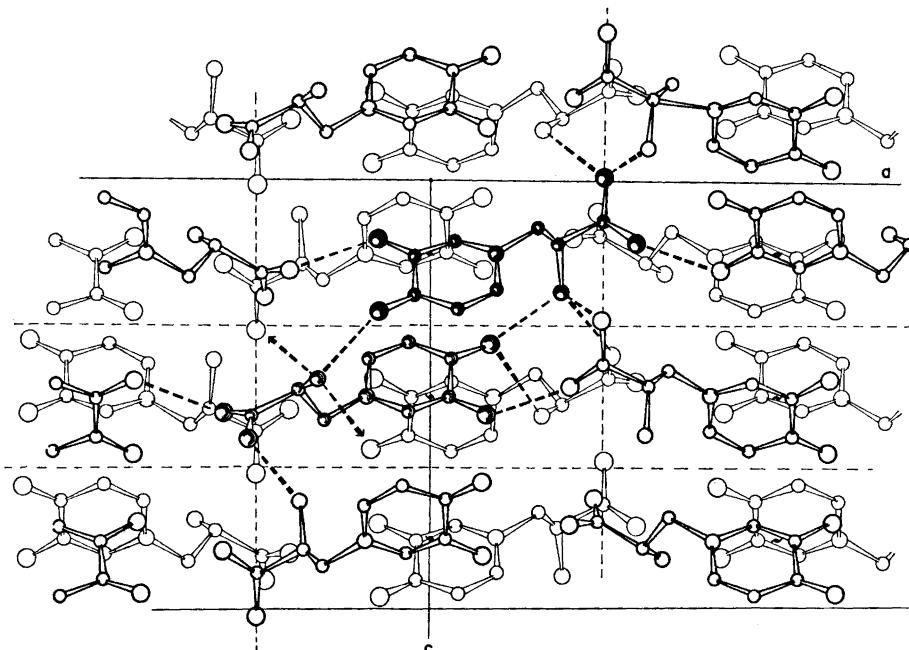

Fig. 3. The crystal structure as seen along the *b*-axis. Hydrogen bonds from one dimer (shaded) are indicated by broken lines.

an electrostatic interaction between the two ring systems owing to their zwitterionic character, and results in a pseudo centre of symmetry between the planar parts of the molecules.

The hydrogen bond system in the crystal is shown in Fig. 3, the hydrogen bond lengths are listed in Table 4. All hydrogen atoms bonded to hetero atoms are engaged in hydrogen bonds, each molecule being involved in eight hydrogen bonds to seven different neighbouring molecules. There is some difference in hydrogen bonding for the two crystallographically independent molecules in that the carbonyl oxygen atom (O1) in the pyridone part is hydrogen acceptor for only one ammonium group, whereas the corresponding oxygen atom (O1*) of the other molecule act as an acceptor of two such hydrogen bonds. Correspondingly, one of the oxygen atoms of the carboxyl group (O3) is acceptor for two ammonium hydrogen atoms and O3* for only one. The nitrogen atom N2 is engaged in hydrogen bonds to two carboxyl oxygen atoms (O3 and O4*) and one carbonyl oxygen atom (O1*); N2* is hydrogen bonded to one carboxyl (O3) and two carbonyl (O1 and O1*) oxygen atoms.

The molecules of type II (*) related by a screw axis in the *b* direction are connected through the hydrogen bonds between O1* and N2*. Similarly, molecules of type I related by a screw axis along *a* are forming chains by means of hydrogen bonds between N2 and O3. Both types of molecules are involved in the hydrogen bonded helix about the screw axis along the *c* direction through the hydrogen bonds O2 – O3* and O4* – N2.
