## Abstract

Graphene quantum dots (GQDs), as a new class of zero dimensional fluorescent carbon material, have been used in physical, chemical and biological aspects for many interesting properties, such as low toxicity, excellent solubility, high chemical stability, and good surface activity. As a green synthetic method, hydrothermal/solvothermal technology has been applied to effectively control characteristics of GQDs. In this review, we summarize recent work on the hydrothermal/solvothermal synthesis of GQDs and their emerging biological applications.

## 1. Introduction

Graphene quantum dots (GQDs), as  $sp^2$ -hybrid single layer nanocrystals, are highly fluorescent in solution or/and film state, even in live cells, due to their quantum confinement and edge effects. The synthetic methods of GQDs mainly include two categories, top-down and bottom-up. Top-down method is based on  $sp^2$ -hybridized carbon materials, such as graphene oxide, carbon fiber, and carbon nanotube, treated with mixed acids [1,2] or by electrochemical methods [3] to cut them into small pieces. Bottom-up method is based on small molecules like glucose [4,5] and citric acid [6] to assemble, polymerize and carbonize to nanoscale product. As shown in Fig. 1, more and more publications have emerged on GQDs, not only in the synthesis of GQDs, but also in their implementation in photovoltaic devices, fuel cells, light-emitting diodes, and bioimaging.

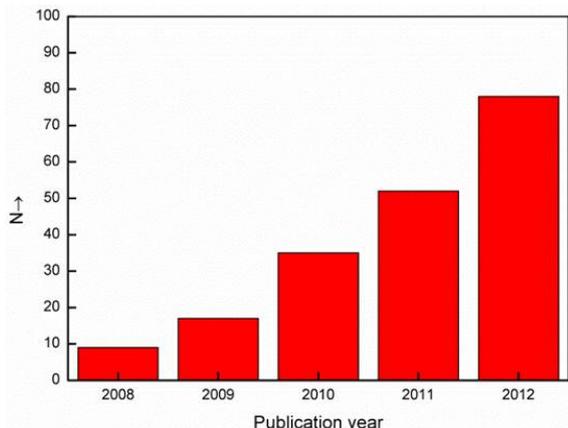

Among many synthetic methods of GQDs, the hydrothermal/solvothermal (H/S) synthesis is the most used one. H/S synthesis is an important technology to produce most inorganic materials. H/S synthesis provides a sealed autoclave environment to form high pressure and high temperature to obtain good crystal morphology. Many carbon allotropes, such as carbon nanotube, nanodiamond, carbon dot, carbon sphere, and carbon aerosol, have been sophisticated synthesized by H/S

reaction. Recent advances on H/S synthetic technologies of GQDs were summarized in Table 1.

## 2. H/S synthesis

Hydrothermal synthesis has a strong influence on the formation and particle size of GQDs. Water, as a green solvent used in hydrothermal synthesis, plays an important role in atom-economical reactions. D. Pan et al. [7] for the first time applied hydrothermal technology to synthesize GQDs. Firstly, graphene sheets obtained by thermal treatment of graphene oxide sheets were cut by mixed acids under mild ultrasonication. Subsequently the treated suspension was transferred to Teflon-lined autoclave to get small GQDs mainly distributed between 5 to 13 nm (average diameter: 9.6 nm). As seen in Fig. 2, the reaction mechanism was proposed to be that epoxy groups and carbonyl groups in the graphene sheets structure were easily fragile and attacked during the hydrothermal deoxidation process. Later, they further modified their method by high-temperature thermally-treated graphene sheets on the strong alkaline condition to prepare well-crystallized GQDs [8].

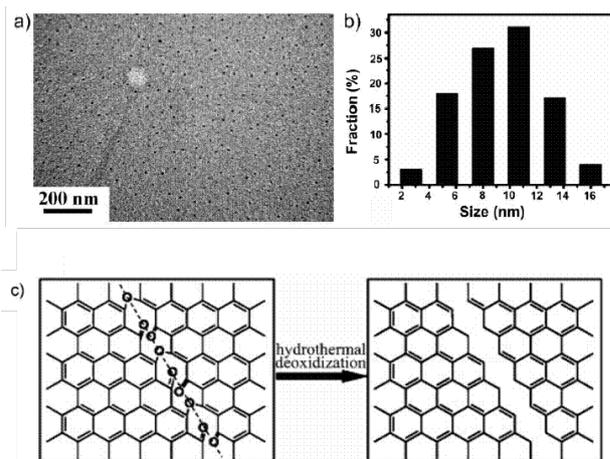

Graphene has attracted tremendous interest in electronics, solar cell, Li-ion battery, and pollution treatment. The modification of graphene, such as N-doping and

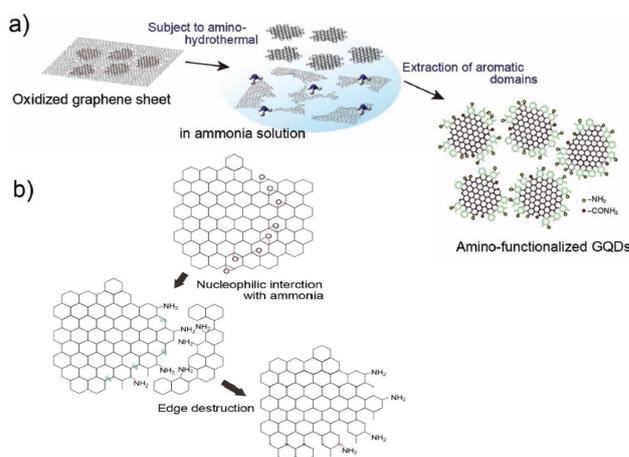

**Fig. 1** The increase in the number of publications about graphene quantum dots based on Web of Science database.

B-doping, may alter its electric properties. Based on the same doping treatment, photoluminescence and electric properties of doped GQDs may be adjusted by changing their band gap. H. Tetsuka et al. [9] reported extraction of amine-functionalized graphene quantum dots (NH<sub>2</sub>-GQDs) using oxidized graphene sheets and ammonia in hydrothermal condition by bond-scission reaction. Photoluminescence color from violet to yellow could be changed by controlling the concentration of ammonia and the hydrothermal temperature. As shown in Fig. 3, nucleophilic substitution is taken place to react with epoxide group to get *sp*<sup>2</sup> domains with ammonia electron-pair's attacking. Whether the reaction temperature was changed or not, the size of GQDs was about 2.7 nm according to Raman spectrum and TEM image.

Y. Liu et al. [10] implemented PAN-based carbon fiber to get 35 nm N-GQDs and then controlled the hydrothermal time in ammonia solution to get 3 nm N-GQDs on the bond-scission strategy using ammonia as a passivation agent. The strategy for synthesis of N-GQDs was illustrated in Fig. 4. Similar work could also be seen in ref. [11] and [12].

Q. Feng et al. [13] demonstrated that fluorinated graphene could be obtained by high temperature treatment with reduced graphene oxide and  $\text{XeF}_2$ , strong acid oxidizing, and finally hydrothermal reaction to obtain fluorinated GQDs (F-GQDs). F-GQDs showed a red-shift by 10 nm compared with undoped GQDs and had an obvious up-conversion photoluminescence that might be used as an effective photocatalyst. Functionalized with small molecules and polymers [5,15], GQDs will tune their luminescence and enhance their biocompatibility.

Microwave-hydrothermal (MH) method is an integrated technology of microwave field and hydrothermal method. Compared with traditional hydrothermal method, MH method can accelerate the kinetics of reaction, shorten the reaction time, and form novel phases. L. Tang et al. [4] used glucose, sucrose, and fructose as carbon source to synthesize water soluble GQDs in a short time under different powers. The obtained GQDs exhibited deep UV emission and had approximately 3.5 nm diameter. As seen in Fig. 5, the reaction mechanism was that glucose molecules were dehydrated to form the core and then edge grew with increasing microwave heating time. Owing to the closed system, the precursor was arranged

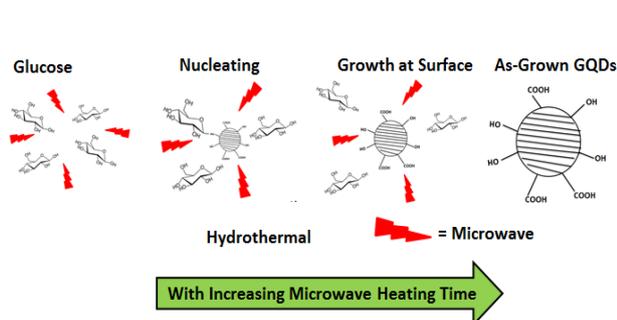

Fig. 5 Preparation mechanism of GQDs by MH method.

to crystalline GQDs.

Recently, L. Tang et al. [5] modified glucose based on MH method using PEG 20000 as soft template and glucose as carbon source. The reaction process went through carbonizing, nucleating, crystallizing, and growing up to finally obtain narrow-size distribution GQDs. S. Chen et al. [17] reported graphene oxide aqueous solution treated with mixed acids in MH method could acquire GQDs. As shown in Fig. 6, in strong acid solution and high concentration, GQDs showed self-assembled J-type aggregation.

Solvothermal reaction is a type of synthetic method using organic solvents (benzene, DMF or DMSO), instead of water to obtain desired reaction products. Because the organic solvents have an important effect on the size and morphology of products, it is necessary to check the chemical nature and physicochemical properties of the solvents. S. Zhu et al. [18] used DMF as a solvent and weak reduction agent to split graphene oxide into the fluorescent green GQDs. The GQDs were obtained by column chromatography on silica gel instead of dialysis treatment. Later on, they increased the reaction time to 8 h, used methanol/methylene chloride and water as

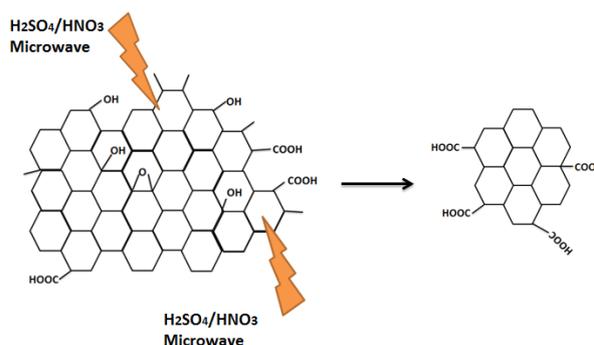

Fig. 6 Oxidation cutting of graphene oxide into GQDs by mixed acids.

http://nanobe.org

mobile phase to get GQDs [19]. It was interesting that the obtained GQDs had the same size and height but different fluorescent absorption peaks. Their fluorescence mechanism was attributed to energy traps.

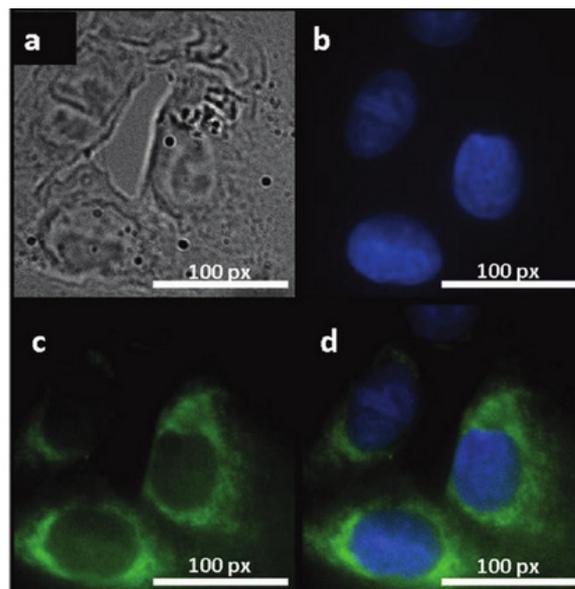

### 3. Biological Applications

#### 3.1 Cell/Tissue imaging

GQDs have more advantages for cell imaging due to their low cytotoxicity, good biocompatibility and excellent photostability. The recent work was summarized in Table 2.

J. Peng et al. [26] evaluated the cytotoxicity of two kinds of GQDs with green and blue fluorescence by using two different human breast cancer cell lines MDA-MB-321 and T47D with MTT viability assay. These GQDs didn't impose obvious cytotoxicity the same as those in other work [18,24]. As shown in Fig. 7, images visualized the phase contrast image of T47D cells, the nucleus stained blue with DAPI, agglomerated green GQDs around each nucleus and overlay image of cell with phase contrast, DAPI and green GQDs.

Y. Dong et al. [1] performed MCF-6 cells as bio-imaging cells exhibiting a bright green color when imaged on the confocal laser scanning microscope. GQDs labeled not only cell membrane and the cytoplasm, but also the nucleus. This was the first time for using photoluminescence carbon nanostructures to label the cell nucleus. L. Deng et al. [29] used hybrid Au NCs@SiO<sub>2</sub>@GQDs nano-composites binding with anti-EGFR (epidermal growth factor receptor) to selectively image cell membrane.

**Fig. 7** Fluorescent images of human breast cancer cell T47D after incubation with green GQDs for 4 h (a) phase contrast picture of T47D cells. (b) Individual nucleus stained blue with DAPI. (c) Agglomerated green GQDs surrounding each nucleus. (d) The overlay high contrast image of nucleolus stained with blue DAPI and GQDs (green) staining. Copyright permission from ref. [26].

Up-conversion photoluminescence is less harmful to living cells or biosystems than one-photon UV or blue excitations. S. Zhu et al. [22] reported up-conversion photoluminescence of GQDs exploring in cell imaging. As shown in Fig. 8, it was found that bright green or blue area inside MC3T3 cells labelled under near infra-red excitation (808 nm), indicating successful translocation of GQDs through cell membrane.

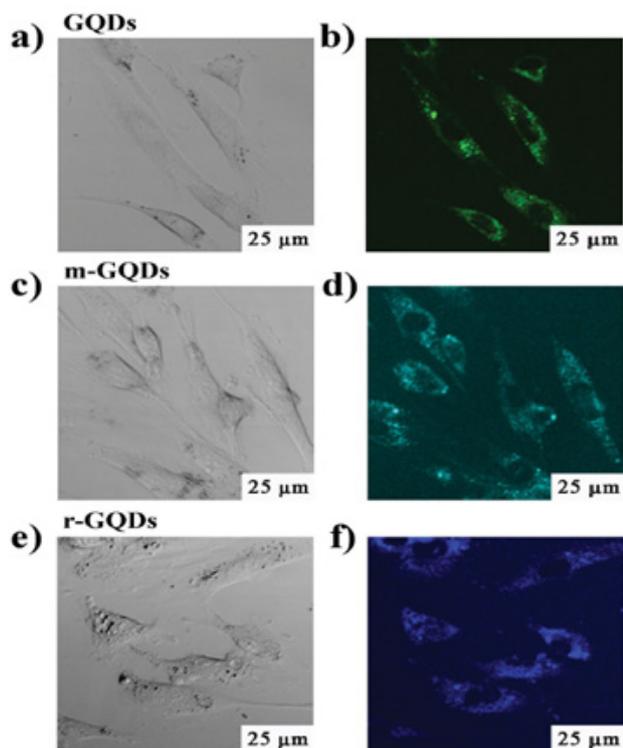

**Table 2** Summary of recent works on cell imaging of GQDs methods.

**Fig. 8** The up-conversion cellular imaging of GQDs. The washed cells imaged under bright field (a, c, e) and 808 nm excitation (b, d, f). The detection wavelength was in the 490-550 nm range for GQDs, 450-500 nm for modification GQDs, and 420-460 nm for reducing GQDs. Copyright permission from ref. [22].

Although many separation technologies [31,32] and synthetic methods [33] have been reported on carbon dots, there are few work on synthesis of long-wavelength and multicolor GQDs. Recently, M. Nurunnabi et al. [30] reported treating carbon fibers in mixed acids and citric acid to obtain near infra-red GQDs by controlling the ratio of mixed acids and the reaction temperature. They performed these particles to image cells, even nude mice. GQDs as a noninvasive imaging agent can be detected at the heart, liver, spleen and kidney at 8 h post injection.

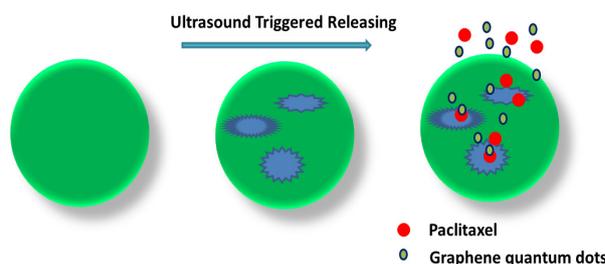

Recently, two-photon deep-tissue imaging was demonstrated by Q. Liu et al. [20]. N-GQDs could achieve a large depth of 1800  $\mu\text{m}$ , which extended the fundamental imaging depth limit of two-photon microscopy.

### 3.2 Drug delivery

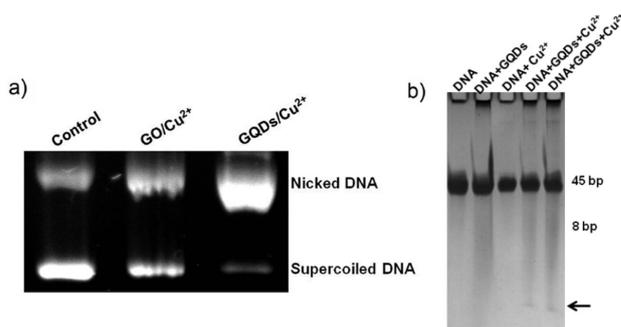

GQDs had been applied to drug delivery combined with targeted drug by weak interaction reported by X. Sun et al. [34]. Y. Jing et al. [35] reported a multifunctional capsule platform for simultaneous fluorescence imaging, magnetically guided delivery, and ultrasound-triggered releasing, which was fabricated by two coaxial electro-spray immiscible liquids. As a tracer for capsule targeting and a marker for drug releasing, the role of GQDs was luminescence imaging (Fig. 9).

### 3.3 DNA intercalator

The choice of DNA cleavage is of importance for understanding the mechanism of DNA scission, repair, and signal transduction. X. Zhou et al. [36] reported

**Fig. 9** Schematic illustration for procedures of shell cracking and drug release under ultrasound.

**Fig. 10** a) Agarose gel electrophoresis of GO and GQDs with  $\text{Cu}^{2+}$  incubated for 2 h at 37  $^{\circ}\text{C}$  in 50 mM Tris buffer (pH 7.2).  $\text{Cu}^{2+}$  was 10 mM, GO and GQDs were both 50  $\mu\text{g}/\text{mL}$ . b) SDS-PAGE of a short DNA helix (45 bp) cleaved by GQDs and  $\text{Cu}^{2+}$ . The arrow indicated the small fragment. Copyright permission from ref. [36].

that using GQDs/ $\text{Cu}^{2+}$  as a DNA intercalator was better than using GO/ $\text{Cu}^{2+}$  which they previously worked [37]. While 59% supercoiled DNA was cleaved by using GO/ $\text{Cu}^{2+}$ , 90% supercoiled DNA was converted into nicked DNA by using GQDs/ $\text{Cu}^{2+}$ . As seen in Fig. 10, when a short DNA helix (45 bp) was used, GQDs/ $\text{Cu}^{2+}$  could cut short duplex into small fragments. While in other control experiment, no small pieces was observed.

### 3.4 Other biological applications

Z.M. Markovic et al. [23] reported that GQDs produced by electrochemical methods showed morphological and biochemical characteristics of both autophagy and apoptosis owing to generating reactive oxygen species when irradiated. It was potential that GQDs could be used as an autophagy-inducing photodynamic agent. X. Chen et al. [38] used GQDs to stabilize i-motif structures under acidic conditions. In addition, under alkaline or physiological conditions, GQDs could promote the formation of i-motif structures. H. Zhao et al. [39] provided a novel signal transduction strategy between graphene and GQDs for the sensitive detection of human immunoglobulin G (InG) based on fluorescence resonance energy transfer (FRET). Glutathione-functionalized GQDs could be used to estimate ATP level in cell lysates and human blood serum as selective fluorescence probes [40]. F. Jiang et al. [41] reported that  $\text{NH}_2$ -GQDs as an anticoplasma agent protected cells from infection due to their peroxidase catalytic activity.

#### 4. Conclusions

Using the hydrothermal, microwave-hydrothermal and solvothermal technology, GQDs can be synthesized with different sizes and tunable fluorescence. With the deep research on GQDs, different methods and technologies may grow up and enlarge the research scope. Due to low toxicity and high fluorescence, GQDs have been used in cell imaging, drug delivery, DNA intercalator, and so on. It is believed that more novel biological applications will emerge in the near future.
