FOREWORD

The National Standard Reference Data System provides effective access to the quantitative data of physical science, critically evaluated and compiled for convenience, and readily accessible through a variety of distribution channels. The System was established in 1963 by action of the President's Office of Science and Technology and the Federal Council for Science and Technology, with responsibility to administer it assigned to the National Bureau of Standards.

The System now comprises a complex of data centers and other activities, carried on in academic institutions and other laboratories both in and out of government. The independent operational status of existing critical data projects is maintained and encouraged. Data centers that are components of the NSRDS produce compilations of critically evaluated data, critical reviews of the state of quantitative knowledge in specialized areas, and computations of useful functions derived from standard reference data. In addition, the centers and projects establish criteria for evaluation and compilation of data and make recommendations on needed improvements in experimental techniques. They are normally closely associated with active research in the relevant field.

The technical scope of the NSRDS is indicated by the principal categories of data compilation projects now active or being planned: nuclear properties, atomic and molecular properties, solid state properties, thermodynamic and transport properties, chemical kinetics, and colloid and surface properties.

The NSRDS receives advice and planning assistance from the National Research Council of the National Academy of Sciences-National Academy of Engineering. An overall Review Committee considers the program as a whole and makes recommendations on policy, long-term planning, and international collaboration. Advisory Panels, each concerned with a single technical area, meet regularly to examine major portions of the program, assign relative priorities, and identify specific key problems in need of further attention. For selected specific topics, the Advisory Panels sponsor subpanels which make detailed studies of users' needs, the present state of knowledge, and existing data resources as a basis for recommending one or more data compilation activities. This assembly of advisory services contributes greatly to the guidance of NSRDS activities.

The NSRDS–NBS series of publications is intended primarily to include evaluated reference data and critical reviews of long-term interest to the scientific and technical community.

Lewis M. Branscomb, *Director.*

Critical Micelle Concentrations of Aqueous Surfactant Systems

Pasupati Mukerjee* and Karol J. Mysels**

Critical micelle concentrations (CMC's), have been collected, organized and evaluated. The literature has been scanned for numerical values from 1926 up to and including 1966. In addition, over 800 values, hitherto available only in graphical form or implied in experimental data, have been extracted from the publications and are included. Close to 5,000 entries, based on 333 references, dealing with 720 compounds are tabulated in the main tables. Whenever available, the temperature, any additives present, the method of determination and the literature source are given for each CMC value and an indication of the apparent quality of the preparation and method used are included. A shorter table gives selected values which are believed to be particularly reliable, including highly accurate ones. Among these, concordant values from at least two independent laboratories are emphasized.

Included in the Introduction is a general discussion of the importance and significance of CMC values and of methods for their determination, as well as a summary of the procedures used in the collection, evaluation and presentation of these values in the present work. Extensive indexes are provided.

Key words: Association colloid; bibliography; CMC; colloid; colloidal electrolyte; critical concentration; critical micelle concentration; detergent; hydrophobic bonding; Krafft point; long chain compounds; micelle; paraffin chain salts; selected values; soap; solubilization; standard values; surface active agents; surface chemistry; surface tension; surfactant.

1. Introduction

Critical micelle concentrations are here to stay! This conclusion is evident from figures 1 to 3 which are based on the literature used in this work. They show a continuing growth since the middle thirties in the number of articles appearing each year which contribute new values and in the number of new values reported. The number of new values per article seems to have passed its peak, which suggests more careful and critical work in recent years.

The reason for this growth is that a critical micelle concentration (CMC) is probably the simplest means of characterizing the colloid and surface behavior of a surfactant solute, which in turn determines its industrial usefulness and biological activity, and gives a measure of the structurally interesting solute-solvent and solute-solute interactions. However, these published CMC values are widely scattered through the literature—we have consulted 87 different publications—and vary greatly in quality from clearly erroneous data to highly accurate values.

Furthermore, some of the existing values are clearly tabulated, but others—often the best ones—are hidden in graphs, or even in tabulations of some measured property such as conductivity. These require considerable effort and judgment to retrieve. Frequently, the quality of the work cannot be judged without consultation of several references and intercomparison with other pertinent publications. Hence, much of the literature is not now readily accessible or useful to those interested in learning what has been established thus far.

The primary purpose of this publication is to provide a list of values in which the user can place high confidence. In the process of obtaining these, we had to make a survey, as complete as possible, of all available values. To present the results of this survey so as to make both the literature and the results contained therein readily available became, therefore, a secondary objective. Perhaps the best evidence for the usefulness of this effort is that nearly two-thirds of the best data reported herein were not previously directly available in the literature but required at least some, and often quite extensive, interpretation of a publication or individual correspondence.

The book itself is divided into four parts:

(1) The Table of Recommended and Selected Values lists the values we believe to be most reliable. They contain further guides to the quality of the data.

*Present address: University of Wisconsin, Madison, Wisconsin 53706.
**Present address: Gulf General Atomic, Inc., P.O. Box 608, San Diego, California 92112.

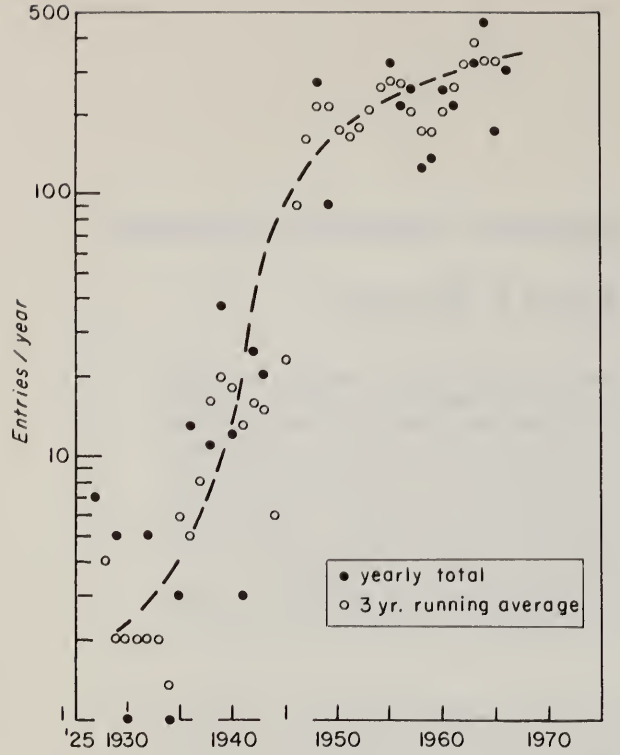

FIGURE 1. *Number of entries for the complete tables originating within each year from 1927 to 1966.*

There are no entries in 1928, 1931, 1933, 1934, 1937 and 1945.

(2) The Complete Table contains all values found which were published through 1966.

(3) Several indexes and lists, particularly the compound indexes, should permit the reader to find any desired compound or its closest analogs, give him the meaning of any abbreviation or symbol, and also guide him to the pertinent literature.

(4) The Introduction discusses the thoughts that went into the collection, evaluation, and presentation of the data. A glance at "How to Use These Tables" may be helpful before consulting them.

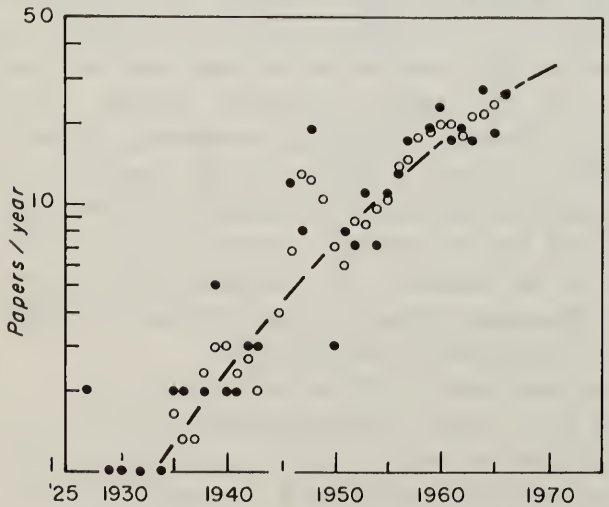

FIGURE 2. *Number of papers containing at least one entry for the complete tables originating within a given year.*

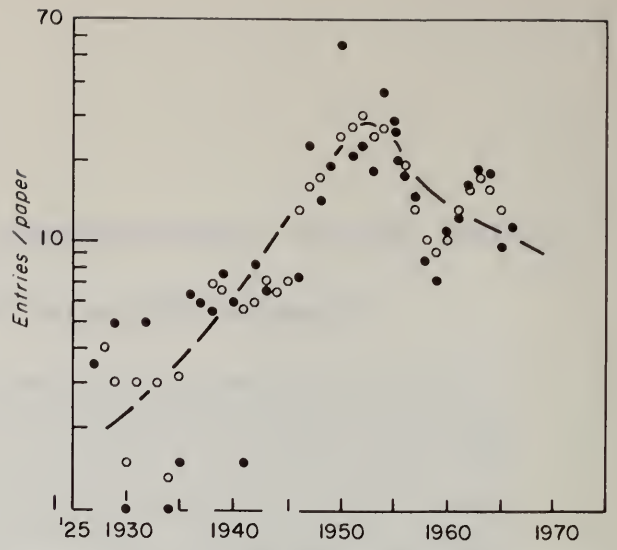

FIGURE 3. *Average number of entries per paper containing at least one entry within a given year and within a three year period.*

The largest number of entries from a single paper was 167, from reference 55004.

We hope that this work will make us more friends than enemies. We tried to be objective in the evaluation of the data, but some errors and personal prejudices are unavoidable. Our evaluation procedure of the individual data is described in the introduction, which contains also general considerations about the validity and significance of the various methods of determination.

We are grateful to many who have helped us in this work. Close to a hundred authors have responded to our request for reprints and many have provided additional comments, data, and interpretations. Dr. Edward L. Brady was most helpful in getting us started properly in the task of handling this multitude of data. Dr. H. J. White's patience and cooperation are greatly appreciated. The extensive computer handling of the data was made possible by the free availability of the data processing facilities of the R. J. Reynolds Tobacco Co., and the programming skill and understanding of Mr. Bill Donovan. Several secretaries have been involved in the careful verification of the hundreds of thousands of bits of information recorded. Mrs. Jerry Wilson and Miss Judy Tate were particularly involved in the final stages. The work leading to this publication was begun in 1964 at the University of Southern California under contract with the National Bureau of Standards and continued there until September 1966 when the authors transferred to their present connections with the University of Wisconsin, where the support of the National Bureau of Standards continued, and the R. J.

Reynolds Tobacco Co. Clearly, the resources of these three institutions made the completion of our work possible.

2. How to Use the Tables

This section presents a brief guide to the admittedly complicated arrangement of the tables. Space and computer requirements dictated much of this complexity; some is inherent in the dissimilarity of the compounds and the variety of conditions used for CMC determinations. The guide is arranged to answer a series of questions which may be raised by readers.

How do I find the compound I am interested in? In the tables the compounds are arranged in numerical order by arbitrary "Compound Numbers." To find this number you must go through the "Compound Index" in which the listed compounds are arranged by structure. There are five parts to this index (plus an alphabetical one for commercial names) and in each the compounds are listed according to different structural properties. These arrangements are described on the first page of the compound index (p. 23).

What can I do if my compound is not listed? The indexes will lead you to the most closely related compounds that are listed. These should permit you to make a good guess by interpolation and extrapolation.

How do I learn about the effect of an additive? The names of additives are abbreviated (if the abbreviation is not clear, its meaning can be found in the list on p. 222). Surfactant additives are indicated by their "Compound Number." For each compound, CMC values in the presence of additives are listed after the simple (surfactant-water) system in alphabetical order of the abbreviations. This is followed by systems with two additives and then by those with three additives.

What if the additive is not listed with my compound? The additive index shows all the compounds reported for any additive. You may find some useful analogies in this way.

What is the effect of temperature? Within each system (compound-additive(s)) the values are arranged by increasing temperature. By checking the author, or better the reference column, you can locate groups of values that were obtained specifically to show the effect of temperature (which is often small).

Which are the "good" CMC values? The shorter tables beginning on page 51 contain the "Selected" and "Recommended" values (15% of all reported values). Those that carry a "1" in the last column have been independently confirmed and should be highly reliable (to 1.5%, keeping in mind that different methods can give significantly different values—cf. p. 11). Those marked "2" are of the same apparent quality but lack confirmation. Among those marked "D" for each system, there is probably one that is as good as those of the preceding categories, but we do not know which. The many marked "3" do not seem to be in the same class but should be good to 10 percent.

What do I find in the long tables? These tables beginning on page 66 contain all the "Recommended and Selected" values plus all the others that we have located. In a number of cases, indicated by "R" in the last column, we make references to the literature where additional data or calculated values may be found or to warn the reader that the values are duplicates of those already listed or are in error. The bulk of the values carry an "L" in the last column. These may be useful and some may be excellent but we could not "recommend" or "select" them for a variety of reasons. Some clue to these reasons may be found in the "quality" column.

What is the "quality" column? In this column the first letter refers to the material and the second to the measurement. The meaning of the letters may be found on page 6. In general the quality decreases in alphabetical order. It represents our opinion after a careful study of the reference.

Are there more data in the literature? Our search does not cover anything published in 1967 or later (including the 1964 Congress of Surface Activity which did not appear in print until 1968). There are also older references that we may have overlooked. All the references within this field that we have scanned are listed in the literature index starting on page 213 whether they have yielded any entries or not. We would like to be informed of overlooked articles. Some of the literature scanned does contain data which, if properly interpreted, could lead to a CMC value which is not included. We have made such interpretations in many hundreds of cases, but not always. However, if a CMC value was mentioned as such in the article, we have tried to include it in all cases.

What are those various "methods"? The "method" column contains generally an abbreviation of the

method by which the CMC value was obtained. These methods are discussed briefly (and their abbreviations given) on pages 8 to 11. The "methods index" lists the references which have used each. These references should be consulted for details.

Occasionally the methods column contains information about the literature or a cross-reference. This is only the case when the entry does not give a CMC value.

In what units are the CMC's? We have followed the references except for order of magnitude conversions (e.g., from millimoles to moles) and as a result have a large number of units. The meaning of the abbreviations is given on page 222 and in the footnote to the table. For noncommercial compounds, for which a molecular weight is likely to have meaning, we have added a value in moles (per liter or kg of solution or kg of solvent) when the corresponding weight concentration of the compound was given. This was done by the computer on the basis of the molecular weight listed for the compound which in turn was also obtained by the computer from a structural or empirical formula of the compound. The value is printed by itself on a separate line below the value given by the author and is characterized by "M" in the "source" column.

What units are used for additives? The same units and symbols as for CMC's plus a number of others, including such peculiar ones as pH, again following the authors. In addition, we have used the additive columns to record certain special conditions such as pressure. The meaning of the abbreviations is listed on page 222. For additives we have not made any conversions to mole units.

What compound nomenclature is used? We have generally followed the first author whom we encountered dealing with the particular compound in the hope that this will also be the most common and understandable name. In case of ambiguity or some exotic names, we have added an alternative name or a formula in parentheses.

Are there any values for solvents other than water? If the solvent is a mixed one including water, the other components have been considered as additives. Nonaqueous systems have not been included for reasons discussed on page 18 with the exception of D_2O which is treated as an additive at 100 mole percent concentration!

What is the meaning of "source"? This column serves to indicate in what way the pertinent CMC value was obtained by us. The meaning of the abbreviations is listed on page 222. In some cases the reader can check our listing directly or after carefully reading a graph or replotting some numerical data. In a few cases, however, our listing is based not only on what appears in the article but on correspondence or conversation with the authors. In this case an L in the source column is given. We have not included, however, values made available to us privately which did not have a basis in the published literature.

Where do these CMC's come from? The exact reference may be found in the Reference index starting on page 213 through the number in the "reference" column of each entry. However, much information can be obtained from this number itself since the first two digits give the year of publication and from the "authors" column which carries the first four letters of the name of the author or two of the authors of that publication. Particularly for those familiar with the field, this should often permit identification of the reference.

Are the numbers of digits really significant? Not in the great majority of entries. We have again followed the authors for the sake of the record and it is clear that most authors paid no attention whatsoever to the rules pertaining to significant figures. A better idea of the precision of the values is given by our "quality" rating of the method (second letter). See page 6 for the approximate meaning of these letters. When the value quoted is obtained by ourselves from published graphs, etc., the significant figures refer to how well these graphs could be read or interpreted without digging further into the uncertainties of the experiment.

3. Usefulness of CMC Value

The expression critical micelle concentration (CMC), as will be discussed later, is slightly misleading because of the use of the singular form of the noun "concentration." The formation of micelles from the constituent monomers involves a rapid, dynamic, association-dissociation equilibrium. Experimentally, it is found, in accord with the expectations from such equilibria, that micelles are undetectable in dilute solutions of the monomers, and become detectable over a narrow range of concentrations as the total concentration of solute is increased, above which nearly all additional solute material forms micelles. The concentration at which the micelles become first detectable depends on the sensitivity of the experimental probe used. The concentration range over which

the fraction of additional solute which forms micelles changes from nearly zero to nearly unity depends on such factors as the number of monomers in the micelle, the chain length of the monomer, the properties of counterions and other details affecting the monomer-micelle equilibrium. An approximate rule is that the higher the CMC value, the broader is the concentration range over which this transition takes place, in absolute value as well as in relative value in comparison to the CMC. Since different experimental methods may reflect this transition to different extents, some systematic variations in operationally defined CMC's are expected, as discussed in more detail later (p. 11).

Nevertheless, in spite of these various sources of uncertainty in defining and pinpointing the CMC exactly, the range of uncertainty is often no more than ±1 to 2 percent of the CMC value. Thus, the CMC is a quantity which can be, and often is, determined experimentally to a much higher precision and accuracy than nearly any other property which is characteristic of solutions of surface-active agents, a point we would like to emphasize strongly. For comparative purposes, in careful work, the precision is often within ±1 percent.

The usefulness of CMC values in various qualitative and quantitative investigations involving surfactant solutions arises basically from the fact that the surface and interfacial activity of the amphipathic (polar-nonpolar) monomers is closely reflected in the value of the CMC. The tendency to form micelles arises mainly from the presence of a hydrophobic part in the amphipathic monomers. The role of the hydrophilic part, nonionic, zwitter-ionic, or ionic (with associated counterions), which is essential for conferring enough of a solubility to the hydrocarbon chain so that CMC values can be reached or exceeded, is essentially a negative one as far as the stability of micelles is concerned. The same factors are involved qualitatively in the surface activity of the monomers, irrespective of whether the surface is an air-water interface, oil-water interface, or a nonpolar solid-water interface. There is thus an excellent correspondence between the adsorbability of the monomers, their ability to reduce surface and interfacial tensions, and the value of the CMC [*1*, *2*].[1] The more surface active the monomer is, the higher is the tendency to form micelles and the lower the CMC value. Since above the CMC the monomer activity rises only very slowly, the CMC is also a measure of the concentration at which the thermodynamic activity of the monomer and, therefore, its net surface activity and adsorbability to various substrates, level off to nearly constant values [*1–3*]. In closely comparable systems, particularly if the hydrophilic moiety of the monomer is kept the same and the hydrophobic part is varied, there is a considerable similarity in the amount of adsorption to air-water and oil-water interfaces at concentrations close to the CMC. It is thus often possible to obtain rough estimates of equilibrium monolayer concentrations from the CMC values in homologous systems [*1–3*].

Since adsorption from surfactant solutions is involved in widely ranging systems of technical importance such as foams, froths, emulsions, suspensions, and surface coatings, CMC values are important in a wide variety of industrial operations [*4*, *5*].

In striking contrast to monomers, the micelles, which have a hydrophilic exterior, are not surface-active. As a result, above the CMC, excepting in some cases where small micelles form and the monomer activity increases appreciably, the surface and interfacial tensions decrease very little [*1*, *2*, *6*]. The CMC, therefore, indicates the concentration at which surface and interfacial tensions reach, approximately, their lowest values. Characteristic values at room temperature are often about 35 dyn/cm for surface tensions and 5 dyn/cm for interfacial tensions.

The CMC, of course, is the concentration at which the micelles make their first appearance. Micelles provide in many ways one of the most convenient systems available to study in depth the properties of colloids. As the properties of micelles depend on micelle-medium interactions and also micelle-micelle interactions, to understand the former without the latter complication, it is necessary to extrapolate properties of micelles to a point where micelle-micelle interactions become negligible. The corresponding extrapolation of preformed colloidal systems, such as polymers or proteins, which do not dissociate on extensive dilution, is made to "infinite dilution." For micellar properties, the CMC serves as a convenient point for extrapolation, i.e., "infinite dilution" for micelles. Just as binary protein-protein interactions (i.e., those involved in second virial coefficients) are experimentally determined from the slopes of curves as they approach infinite dilution, so in micellar

[1] Italicized figures in brackets indicate the literature references on page 20.

systems, the corresponding concentration range is the one just above the CMC [7–10].

In systems involving solubilization of an additional component or its distribution between the bulk solution and the micelle, the CMC again is a measure of the concentration at which such phenomena become first apparent. It will be discussed later that the addition of the third component may modify the CMC itself to some extent and, therefore, the CMC of the system in presence of the third component is the value to be used. The change in the CMC, however, is often small.

In situations where a quantitative estimate of the amount or concentration of micelles is desired, for example, in estimating solubilizing powers, or the effect of micelle concentrations on the chemical reactivities of constituent monomers or solubilized species, an area of research which is of considerable current interest [11–15], the CMC again serves the purpose of giving a rough estimate of the monomer concentration in the solution. The micelle concentration in equivalents, therefore, can be closely approximated as the total concentration minus the CMC.

For the quantitative study of the thermodynamics of the interactions involved in the monomer-micelle equilibrium, the CMC is of paramount importance [16–21]. Although considerable uncertainties still exist with regard to the proper means of estimating the charge effects in ionic micelles, for uncharged systems the CMC itself gives an approximate quantitative measure of the standard free energy of formation of micelles. These free energies and other derived thermodynamic quantities are of great potential and actual use in understanding hydrophobic interactions in general [22–24]. Such interactions are involved in a wide variety of biochemical phenomena, e.g., the stability, structure, conformation, and activity of proteins, enzymes, and membranes. With ionic micelles, as mentioned before, the calculation of thermodynamic quantities characterizing the various interactions is not on sure ground as yet. For comparison of related systems, however, e.g., in noting the effect of varying the chainlength, salt concentrations, or counterions, the CMC provides quite a good quantitative measure of the changes as they affect the monomer-micelle equilibrium [8, 18, 25].

4. Evaluation

An important part of this work is the evaluation of the data presented. We hope to guide the reader to those data that are most useful and reliable in our considered judgment and also to show him other values that exist in the literature so that he may make more easily his own evaluation. We also tried to indicate the relevant literature and data that we have considered but not used in final listings.

We divided our evaluation into two steps: one, which we may call the individual or preliminary evaluation; the other, the comparative evaluation. The former represents our opinion on the basis of the individual paper (and its references or related papers of the same author); the latter is based on intercomparison of all the available data for a given compound under the same, or closely related, conditions. The former was done as the work progressed over a period of three years, 1965–68, and, therefore, is subject to the drift and development of our ideas and skills during that time. The latter was done in a short period of time after all the data had been collected and sorted by the computer.

Individual evaluation. A preliminary separation involved the question whether a given CMC value should be reported in detail or not. Values which are indicated in the article as being duplicates of other published values are omitted completely. Others, however, which are clearly duplicates but not explicitly indicated as such by the authors, are mentioned as "VALUES FROM REF IN CMC," with the article from which they are taken listed in the column in which the CMC is normally found.

Values which could not be retrieved profitably, e.g., those in the form of small-scale graphs or summarizing equations, are indicated as "GRAPH DATA NOT RETRIEVED" and "SUMMARIZING EQN ONLY" for the reader who wishes to examine them himself. There are 41 entries in the former category and 22 in the latter.

Once a value was included explicitly, we attempted to evaluate the purity of the materials and the accuracy and precision of the method used. These were noted separately as reported in the "Quality" Rating columns. The meaning of the symbols is as follows:

MATERIAL	METHOD
A Highest purity—not likely to be significantly improved in the future	precise to about 1% accurate to 1.5%

B	Very pure but may still contain significant traces of impurities	precise to about 2% accurate to 3%
C	Purified but likely to contain significant impurities	precise to about 3% accurate to 5%
D	Compounds purified without special precautions against surfactant impurities	precise to about 10% accurate to 10%
E	Good quality mixture of head groups	order of magnitude
F	Good quality mixture of homologues	wrong
G	Not purified	likely presence of systematic errors of uncertain absolute and relative magnitude
H	Commercial surfactant material	
P	High purity claimed without supporting data	
Q		theoretically calculated
X	No information given	

These ratings should be taken with certain reservations, both because of the possibility of personal bias and of the frequent lack of all the information required to form a definite opinion, and the unavoidable lack of consistency over the four-year span during which they were being assigned. All that can be said is that they represent our best opinion at the time of a detailed reading of the article cited. Because the evaluation was individual, it is not surprising that upon later comparative evaluation, some values which were initially ranked high appeared more questionable or vice versa. Hence, the ratings are at best meaningful to plus or minus one category. We may mention, however, that during the final evaluation we frequently referred to the original papers, and only in two cases did we feel the need to change the preliminary ratings.

Comparative Evaluation. This evaluation was performed after all the data were collected and classified by the computer into the form of the "Complete CMC Listing" of this report. This permitted easy intercomparison of values reported for the same or similar systems. Each value was then assigned to one of a set of categories. This assignment also formed the basis for obtaining the "confirmed," "recommended," "disputed," and "selected" values for a separate listing.

The following categories were used:

1-Confirmed.—Values from at least two independent laboratories which are of good quality both with respect to materials and methods and which agree within the expected limit for a given method or between methods. These may be used with high confidence.

2-Recommended.—Values of the same quality as above but lacking independent confirmation.

D-Disputed.—These are values which seem as accurate as the preceding ones, but disagree by more than would permit them to be classified as "confirmed." It is likely that one of the values is correct but we did not have a firm basis for deciding which. In some cases correlation with values for other systems indicated a definite choice and the preferred value was assigned a "2," i.e., "recommended" rating, and remaining values were assigned the "L" or "literature" rating.

3-Selected.—These are values which do not appear to have the accuracy of the above categories but should still be of considerable utility. We feel that they are probably within 10 percent of the "true" value, as measured by the same approach. Their total number is less than 10 percent of all the entries, and they represent the next most reliable group after (1) and (2).

L—Literature.—This category includes the great majority of the values. They are provided for bibliographical completeness and because some readers may prefer any value—no matter how unreliable—to no value at all. Some of these values may be accurate, but there is insufficient information to certify that this is the case. Some will turn out to be off by orders of magnitude. In some cases where the literature provided *prima facie* evidence that the CMC value was erroneously assigned, we have indicated this by the statement "QUESTIONABLE CRITERION" in the "method" column.

P—Preferred.—Occasionally, widely differing values have been reported for what should be a single CMC. The reader's choice can generally be guided by the quality rank assignment to the compound and method. In a few cases we thought it advisable to indicate the preferred value by a P. These data did not qualify for one of the "selected" or "recommended" categories, but seem to be clearly preferable to the others.

R—Indicates a literature reference in which the reader may find a value not tabulated by us. A

statement in the "methods" column indicates whether the reason for omission is that we considered it a duplication (without explicit reference) of a value from another publication, or a value which could not or should not be listed.

X—Indicates a cross-reference within our tabulation and is used for mixed systems of surfactants which are reported only once under one compound but cross-referenced under the others.

In deciding about the probable accuracy of a CMC value we considered not only the details of the particular measurement but also the general validity and limitation of the method used. It may, therefore, be appropriate now to review briefly the multitude of these methods and then to consider some factors which guided us in judging their intrinsic accuracies.

5. Methods of Determining CMC's

Although abrupt changes in the concentration dependence of several properties of several surfactant solutions had been observed before the 1930's [*26–28*] and the concept of micelles in such solutions had been developed by McBain and coworkers [*29*, *30*], the existence of a narrow concentration range, called "the critical concentration for micelles" [*31*], below which the solution contains negligible amounts of micelles and above which practically all additional surfactant is found in the form of additional micelles, was established by Bury and his coworkers [*31*, *32*] and Hartley and his coworkers [*33*] in the early 1930's. Since that time, CMC determinations have multiplied and the results have been used in a variety of ways. The importance of a definite CMC value to which micellar properties could be extrapolated so as to give the infinite dilution behavior of micelles was emphasized by Debye soon after World War II [*34*].

In the process of collecting the present data we have distinguished 71 methods of determining the CMC, ranging from a few widely used ones to a few reported only once. These may be grouped as follows, with the numbers in parentheses giving the number of CMC's in this report for each method or group of methods. Experimental details of these methods may be found by following the references given for each in the index to methods.

The entry "METHOD NOT CITED" (128) in most cases refers to just that, when a CMC value appears with no further indication. In a few cases, however, it results from the fact that the article is not clear as to which of two or three well-defined methods was used in determining each individual value. One or two of such cases deserved, in our opinion, enough confidence to be included among "selected" values.

Also in a special category is the THEORETICALLY ESTIMATED (5) entry which we included for completeness.

The other methods can be divided into two broad classes depending on whether another material is added to the system specifically for the purpose of the measurement (as opposed to an additive whose effect is being studied). They are at present all based on the study of a property of the system as some function of concentration and detection of a particularity, such as a change of slope or a discontinuity, at the CMC.

Methods Requiring No Additive

1. SURFACE TENSION (940). This method of increasing popularity involves the measurement of surface tensions of solutions by a variety of methods which we did not attempt to classify (such as the du Nouy ring detachment method, the Wilhelmy plate equilibrium or detachment, drop weight or volume or shape). The data are generally plotted against the logarithm of concentration—LOG PLOT (843)—as the abscissa and the transition between a descending line (often assumed to be straight) and another one close to the horizontal is taken as the CMC. The data can also be plotted directly against the concentration—LINEAR PLOT (18)—in which case the curvature of the descending portion is much more marked and the transition less sharp. A MINIMUM (15) in the curve is now known to be due to the presence of a third component (contamination or products of hydrolysis) which is more surface active but removed from the surface by solubilization in the micelles above the CMC. It is sometimes reported as the CMC of the system. We have also encountered the UNSPEC (64) where no details are given. Interfacial tension methods are considered later among methods involving an additive.

A related method is based on the FOAMING POWER (2) of the solution. It is not clear at present how the changes in this property are related to the association of monomers into micelles.

2. Electric conductivity—COND or COND-CTNCE (953)—is based on the measurement of the A-C electric resistances of the solutions. These can then be interpreted in terms of the specific

conductivity—SPECFC (386)—and plotted—GRAPH (343)—against concentration to give two almost straight lines whose intersection is the CMC or the data corresponding to each straight line can be summarized by equations—EQUATNS (43)—and the CMC obtained analytically. The data can also be converted to equivalent conductivity—EQUIV (352)—and the CMC obtained graphically—GRAPH (319)—usually plotting against the square root of concentration. Occasionally linear or cube root plots have been encountered. In much early work it was the first detected deviation—1ST DEVIATION (18)—that was reported as the CMC. As the CMC thus assigned depended clearly on the sensitivity of the method, this approach seems to have been abandoned. A few surfactants having low CMC's show a maximum of equivalent conductance in the CMC region. The origin of this maximum is not yet clear [*34a*] and in some cases the beginning of the rise—MAX BEGINING (10)—in others the MAXIMUM (5)—itself is reported as the CMC.

Some authors report averages—AVER (110)—of two of the above methods, namely specific and equivalent—SP EQUIV (104)—conductivities or of the beginning of the rise to the maximum and of specific conductance—COND BEGINING MAXIM (6). Some report results based on conductance without further details—UNSPEC (105).

The variation of electric conductance with frequency at high frequencies, the so-called WIEN EFFECT (1), is different for micelles and monomers and has been used to determine the CMC.

3. There is a variety of methods to investigate optical and spectroscopic properties of a solution, and they may be classified as follows:

(a) Measurements of scattered light—LITE SCATR or LIGHT SCATTER (317) depends on the measurement of the intensity of light at an angle, generally 90°, to the incident beam.

A plot of this intensity or of the turbidity of the solution (which is proportional to it) shows a low slope for dilute solutions and a steeper one above the CMC. The intersection of the two parts on a TURBIDITY PLT (291) gives the CMC. Debye has pointed out that the concentration above the CMC divided by the turbidity (or excess turbidity above that at the CMC) is close to a straight line. Conversely the CMC may be obtained by selecting the value which gives the best straight line on such a DEBYE PLT (25). In light scattering the exact procedure was not indicated only once—UNSPEC (1).

(b) The CMC can be obtained from the change of slope of the REFRACTIVE INDEX (134) when plotted against concentration.

(c) The absorption spectrum of some surfactants is different when they are in micellar and in free form. Hence, plotting the absorbancy at a suitable wavelength can give a change of slope corresponding to the CMC. This MICELLAR SPECTRAL CHANGE (30) method should be distinguished sharply from the multitude of other spectral change methods in that it does not require any additive.

(d) Others. A CMC has been obtained by the change in the X-RAY DIFFRACTION (1) pattern but this method has a very low sensitivity and, therefore, precision. Another method using a spectroscopic technique which has been introduced after the closing of this survey involves shifts of nmr peaks.

4. Calorimetric methods used to obtain CMC's are those of SPECIFIC HEAT (4) and HEAT OF DILUTION (24).

5. Two colligative properties have been used. FREEZING POINT (14) lowering which gives the CMC at a single temperature, generally close to zero, determined by the nature of the solute and VAPOR PRESSURE LOWERING (38) generally measured with a so-called vapor pressure osmometer based on the temperature comparison of two droplets, one of solution, the other of solvent.

6. The abrupt increase of solubility with increasing temperature which occurs once the solubility reaches the CMC region is the basis of the KRAFT POINT SOLUBILITY (21) method. This change is sharpest when the logarithm of the solubility is plotted against the inverse absolute temperature. Often other plots or even single point experiments are used which have little or no value.

7. Several of what may be called transport properties have been used. They include:

(a) Measurements of the DIFFUSION COEFFICIENT (2) of the surfactant which gives, of course, an average of the very different mobilities of micelles and monomers and leads to a change of slope in a D versus C plot to give the CMC.

(b) The VISCOSITY (9) of the solution plotted as the specific viscosity $[(\eta - \eta_0)/\eta_0]$ or as the reduced viscosity (η_{sp}/c) shows a change of slope at the CMC. A related method depends on an observed VISCOSITY MINIMUM (14) in the CMC region. This minimum probably results from a combination

of surface tension, contact angle, and viscosity effects in the capillary instrument used, so that its relation to the micelle formation is not clear.

(c) Measurements of STREAMING CURRENT (6) have been also used for determining the CMC and should perhaps be classified among methods requiring an additive since these electrokinetic phenomena depend on the adsorption on the solid involved which is specific to the surface. They also depend, though only in a secondary way, on changes occurring in the bulk of the solution which involves the CMC.

(d) Changes in the concentration of the filtrate in ULTRAFILTRATION (9) and in the sedimentation coefficient in ULTRACENTRIFUGATION (1) also lead to CMC values.

8. Potentiometric measurements use several approaches:

(a) ELECTROMOTIVE FORCE (32) methods involve measurements of potential of either specific ion electrodes other than pH ones or of an insoluble mercury-surfactant salt electrode against a salt bridge-reference electrode. It may be noted that the presence of the salt bridge often causes local precipitation of the surfactant and that insoluble salts can be solubilized by micelles. These complications are often overlooked but should, perhaps, cause these methods to be considered with those involving additives.

(b) EMF ALONG CONC GRADIENT (1) uses two closely spaced identical electrodes moved through a solution having a known concentration gradient. Hence, it depends on a change of the slope of the emf—versus—concentration curve.

(c) PH AND HYDROLYSIS (9) method involve pH measurements interpreted either directly or after conversion to a degree of hydrolysis. They are grouped together since they often involve problems of carbon dioxide contamination as well as salt bridges.

9. Other bulk properties that have been used to determine CMC's are density (23) based generally on magnetic float methods plotted directly as DENSITY (17) or after conversion to PARTIAL VOLUME (6) and ultrasonic VELOCITY OF SOUND (10).

Methods Involving the Use of an Additive in the Bulk of the Solution

1. Spectral change—SPCTR CHNGE (1602)—methods.

This family of methods whose limitation (which we consider quite severe) will be discussed below (p. 12) is by far the most fertile one as far as supplying CMC values. It is based on the fact that the spectra of many dyes added in very small amounts to a surfactant solution are very different in the region below and in that above the CMC. Pinacyanole—PNCN (1176)—is also by far the most popular among these dyes. The CMC may be determined, for example, by titration of a solution above the CMC by one below the CMC, both containing the same concentration of dye. Some definite shade is chosen as the end point corresponding to the CMC. Alternatively, solutions having concentrations bracketing the CMC are prepared containing the same concentration of the dye and their color examined visually, or their spectrum or their absorbancy at a specific wavelength measured. In any case, the concentration at which some sharp change occurs is taken as the CMC. In some cases the values are extrapolated to zero dye concentration. For one dye Rhodamine 6G—RHD6 (74) in addition to the spectral change, the change in fluorescence FLUOR CHNGE (19) was used and is based on the same principles.

We have noted whether the technique used was VISUAL (1277) photometric—FOTOMTR (305)—or UNSPEC (20)—as this is related to the precision expected.

Other dyes which have been used in this method are Fluorescein—FL (2), Erythrosin—ERTS (7), dichlorofluorescein—DCLF (9), Benzopurpurine 4B—BZP4 (11), Bromphenol Blue—BRPB (21), Skyblue FF—SKYB (43), Eosin—EOSN (51), Indophenol—INPX (129) and, included because it performs the same function although not a dye in the strict sense, Iodine—12 (52). There is also unspecified VISUAL SPECTR CHNGE (27).

2. The fact that many water-insoluble substances dissolve significantly in the presence of micelles, i.e., are solubilized, has been used in the determination of CMC's by solubilization—SOLUBLZTN (293)—methods. The solubility of dyes has always been determined photometrically—FOTOMTR (274)—unless it is UNSPEC (12), that of TOLUENE (4) has been determined volumetrically, and the limit of solubility of lauryl alcohol has been established turbidimetrically—TURBIDMTR LOH (3)—. The most popular dye is the so-called orange OT—OROT (158)—which is always 1-o-tolyl-azo-2-naphthol, CI Solvent Orange 2, m.p. 128–9°, and not the complicated pigment which was once available under that name which is CI Pigment Orange 13,

m.p. 332°. Other solubilizates used are paradimethylaminoazobenzene—PDMAB (59), Sudan 4—SDN4 (46), azobenzene—AZBA (11), Yellow OB—YLOB (9), 2-nitro-diphenylamine—2NPA (2) and dimethyl yellow—DMYL (1).

3. Methods based on liquid-liquid interface phenomena.

(a) Measurements of INTERFACIAL TNSN or TENSION (52) between an aqueous solution of a surfactant and an immiscible liquid have been used in the determination of the CMC. Most values were obtained from semilogarithmic plots, LOGM (46) but we also found UNSPEC (6). These methods are classified among those requiring an additive because of the always finite solubility of the other liquid in the aqueous phase especially above the CMC. A frequently present source of error in this method is the solution of some of the surfactant in the nonaqueous phase which can radically change its real concentration.

(b) We are placing in the same category methods based on the suppression of the POLAROGRAPHIC MAXIMUM (45) since this suppression is related to an increase in surface (dilational) viscosity of the mercury-solution interface which reduces the convection currents responsible for the maximum in the "diffusion" current. These surface viscosity changes are in turn related to the adsorption of the surfactant and thus depend on its activity. However, it is not clear at present how the final polarographic criterion is related to the CMC. These measurements require also the presence of a very high concentration of an inert electrolyte and that of an electrochemically active indicator ion. This makes the composition of the solutions rather unique and prevents comparison with other data. Although we are quite skeptical about the significance of data obtained by this method, we have reported them in view of lack of any definite evidence of their invalidity. A further disturbing fact is that sometimes two CMC's are reported for a given system. One of them is, therefore, certainly wrong. However, for the sake of completeness we had to record both.

4. Other methods in this class include a result obtained from changes in the FLOCCULATION RATE (1) of a suspension and those from changes in the (reaction) REACTN RATE OF A SOLUBILIZATE (2) as it becomes solubilized above the CMC.

6. Reasons for Methodical Differences Between CMC Determinations

As shown by the above review of methods used, the determination of a CMC involves a series of measurements of some property of solutions of surfactant, alone or with an indicator, as a function of concentration followed by the detection of some characteristic point which is called the CMC. Methodical differences may originate from the choice of the characteristic point, the kind of plot on which this point is chosen, the kind of data which are plotted, and the effect of the indicator, if any, upon these data. We use here the term "plot" in a general sense to include any serial representation and even titration, although in the great majority of cases it is a real graphical plot that is involved.

If the CMC were a sharply defined point, such as a melting point, above which some properties were qualitatively different from those below it, methodical differences would be nonexistent or greatly reduced. In fact, however, all properties of a solution in the CMC region vary in a continuous manner and so do all their derivatives. There is, nevertheless, a relatively narrow region of concentration in which these changes are most marked. This is illustrated by precise measurements on pure systems such as those of figure 4 (and is, of course, exaggerated on impure ones) but is perhaps best

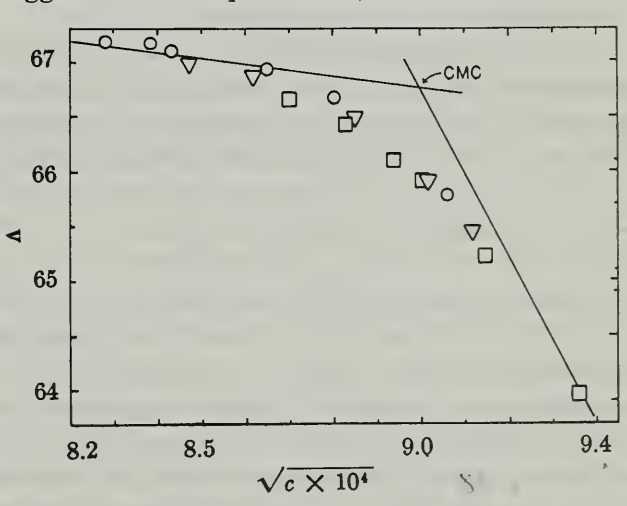

FIGURE 4. *Detail of the CMC region for sodium dodecyl sulfate.* The straight lines are based on many points beyond the limits of the figure. The points were obtained by two investigators on two different preparations of the compound. From reference 58013, reprinted by permission of the Journal of Physical Chemistry.

grounded on broad theoretical considerations. One is that a micelle is by definition a reversible aggregate of a large but not infinite number of monomers and that the micelle-forming reaction must obey the laws of chemical equilibrium. As such, the

concentration dependence of the degree of micellization has to change gradually although it may change rapidly [*32*, *33*, *35*]. A truly abrupt, discontinuous, transition is excluded. Consequently, all properties of the solution must show similarly rapid but gradual changes. Another argument which is less self-evident but seems to be well supported is that there is not a unique number of monomers which can form a micelle but a range with relatively wide limits. Hence, micelles are polydisperse. This is in agreement with the fact that (the average) micellar size varies continuously with conditions such as temperature, concentration of surfactant, concentration of counterion or other additives, nature of counterion, chain length and structure, and also that micelles are good solvents both for other materials as shown by solubilization, and for each other as shown by the frequent continuous formation of mixed micelles. Reasonable assumptions about forces determining the size of the micelle also lead to the conclusion that they must be polydisperse [*35a*]. Hence, in the CMC region not one kind of micelle, but many kinds appear, each with a slightly different concentration dependence which further spreads and complicates the changes of bulk properties occurring in this region.

In light of these considerations, we shall now review in more detail the sources of methodical discrepancies in CMC determinations and their effect upon our critical evaluation.

1. *Choice of the characteristic point.* As already mentioned, in some early work, it was the first detectable deviation from monomeric properties that was taken as the CMC. This depended greatly on the sensitivity of the method and has generally been replaced by an extrapolation from below and from above to a point of intersection. If the two lines are straight and differ markedly in slope, this is a simple procedure. Unfortunately, such is seldom the case. Some of the procedures, therefore, involve a treatment of the data to obtain a straight line. Thus, equivalent conductivity of strong electrolytes is plotted against the square root of the concentration in accordance with the Onsager limiting slope.

It also seems true that those properties which give the best straight lines, because they are rather insensitive to interparticle interactions, also give small differences of slope for the same reason. Density and refractive index or specific conductance in the presence of high salt concentrations are good examples. Hence, they require precise measurements to give useful results. This implies keeping constant all factors other than the concentration of surfactant, such as the temperature, and also the concentration of other components such as added salts. The latter often requires extreme precautions against evaporation. In the interpretation of such precise measurements, difference plots (i.e., experimental value minus a straight line value) are useful. A few methods, however, give good straight lines of very different slopes, e.g., conductance in the absence of high salt concentrations, solubilization of some dyes, or micellar spectral changes of some pyridinium compounds.

Closely related to the extrapolation method is that of the point of maximum rate of change of slope (i.e., zero value of third derivative) which is useful in theoretical calculations [*16*] but is so difficult to apply experimentally that it does not seem to have been used.

In the spectral change methods using indicator dyes there is generally a change of absorbancy at any given wavelength from one characteristic value below the CMC to another above the CMC. Some authors take the beginning, some the end, and most the midpoint of that change. The latter is by far the most objectively defined but, as we shall see later, is a function of concentration of the indicator. In visual methods there is much subjectivity and the result can depend markedly on local illumination because of the very complicated absorption spectrum of certain dyes, particularly the most frequently used one, pinacyanole.

Clearly, depending on which point is defined as the CMC, values covering a considerable range may be obtained. We have given weight only to those methods which defined a point in the middle part of the range, particularly those using an extrapolation procedure, and much of the following discussion will be restricted to those.

2. *The kind of plot chosen.* A point which is not often appreciated is that the same experimental data can give different values for the CMC by extrapolation procedures depending on how they are plotted. The best known example of this is the difference between CMC's obtained by plotting conductance versus concentration and the corresponding equivalent conductance versus the square root of concentration. Figure 5 shows an example of the same set of experimental data plotted in these two ways. Very reasonable linear extrapolations give a well-defined CMC in each case, but the two values

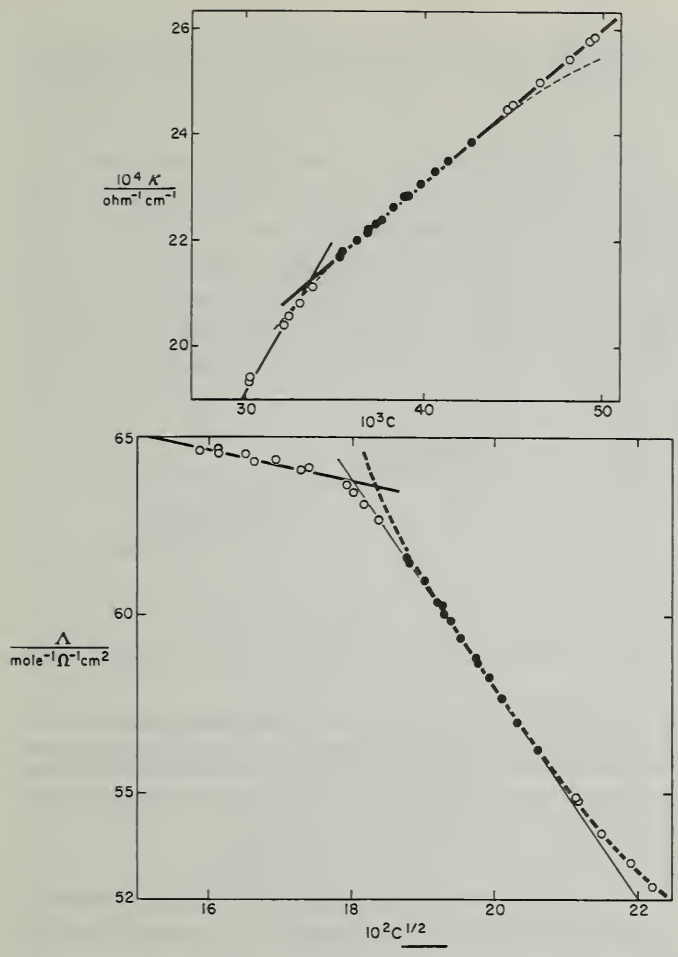

FIGURE 5. *The effect of the way of plotting upon the value of the CMC obtained from the same data.*

Above: conductivity versus concentration; below: equivalent conductivity versus square root of concentration. The dotted curves on each graph correspond to the straight line of the other graph. The filled points are common to both lines. Data for sodium decyl sulfate obtained by Dr. R. J. Otter. From the 14th Technical Report, Office of Naval Research, Contract Nonr-274(00) by K. J. Mysels, R. J. Otter and P. Kapauan, University of Southern California, October, 1960. (Cf. Ref. 61017).

differ by about 3 percent, which is much more than the uncertainty in each. The discrepancy is due in large part to the fact that, a straight line on one plot is a curve on the other so that different points are chosen as the basis for extrapolation and the intersection is shifted.

3. *The kind of data.* If micelles were monodisperse then, for CMC determinations, the molecular weight or charge dependence of a property would not matter as long as it was linear with some function of the concentration. However, if one accepts the premise that polydispersity is possible, it is clear that different physical properties will give differently weighted measures of micellar concentrations and, therefore, different extrapolated values of zero micelle concentration, i.e., different CMC's [*18*]. The most accessible experimental variable is the total concentration of surfactant conveniently expressed in equivalents. We will estimate the kind of average that is plotted against this variable in some popular methods without attempting to discuss this subject fully.

Solubilization. As a first approximation we may assume that the surfactant chains have a constant solvent power independent of their configuration, i.e., independent of the micellar size. The quantity measured—the concentration of solubilizate—is then directly proportional to the equivalent concentration of micellized surfactant and independent of polydispersity. More formally, we call n_i the number of monomers per micelle of a given size, M_i the molar concentration of these micelles, and C_i their equivalent concentration. Each group of micelles then dissolves an amount of solubilizate proportional to $M_i n_i$ and the measured total give us

$$\sum M_i n_i = \sum C_i = C_m$$

where C_m is the total equivalent concentration of micelles. Thus, the result is unweighted.

Colligative measurements. These give the sum of molar concentrations of micelles (for the simple nonionic case). Hence, we get

$$\sum M_i = \sum C_i / n_i$$

the inverse-size weighted equivalent concentration of micelles.

Turbidity. The total turbidity is the sum of the turbidities of the individual micelles and these in turn are proportional to the square of their mass (again neglecting charge effects and other interactions). Hence, we measure

$$\sum \tau_i = \sum M_i n_i^2 = \sum C_i n_i$$

or the size weighted equivalent concentration of micelles.

Thus, it is clear that these different methods must yield different results. Yet, when the polydispersity is small, the micelles large, and the transition region narrow, the differences may be small, often smaller than experimental uncertainties. Thus, depending on the precision involved and the particular system under consideration, the term CMC may have a definite meaning or may have to be tempered by a specification of the experimental method used and also of the way in which the results are interpreted. Unfortunately, there is little definitive information about the final effect that these factors have on the CMC values determined by various methods.

In the final evaluation of the CMC values, we had to face the question whether two numbers obtained under allegedly identical conditions and by apparently reliable measurements did agree sufficiently to confirm each other. In making the decision, we tried to take into account the differences expected between methods in addition to differences due to the unavoidable experimental uncertainty on which we placed an arbitrary limit of 1.5 percent. Hence, two CMC values differing by 4 percent may be taken as comfirming each other, if the methods used would be expected to differ by 3 percent (in the proper direction), as is indeed the case for conductance and equivalent conductivity measurements.

4. *The effect of the concentration range used.* Extrapolation generally uses straight lines. Few physical properties vary, however, exactly linearly. Generally, some curvature is present in reality. Hence, the line drawn tends to be a chord and its direction and position are a function of the portion of the curve that is being approximated. This remains true whether a line is drawn by inspection or after a least square calculation. In terms of CMC determinations, it means that the value obtained depends generally on the range of concentrations above and below the CMC over which the extrapolation is taken and, therefore, the number and spacing of points. There is no general agreement as to what these ranges should be and herein lies another source of discrepancies. Figure 6 shows the effect of the range of data used upon the CMC.

In dilute solutions there are some theoretical guides to the expected curvature which suggest the kind of graph which is likely to make the experimental points fall close to a straight line. The square root for conductivity, the logarithm for surface tension are good concentration scales for monomers, and micellar concentration divided by turbidity is a good one for light scattering. In more concentrated solutions the systems depart more and more from ideality and all plots become nonlinear. Extrapolation then becomes more and more a question of judgment and of the range and spacing of available data, and the CMC value becomes highly subjective. Since compounds with shorter chain lengths tend to have higher CMC's, this is an important factor in reducing the accuracy of CMC determinations as the chain length decreases below 10 carbon atoms.

The CMC region is itself a region of curvature of any measured property. This means that experimental points very close to the CMC cannot be used for its determination because they deviate from both lines used in the extrapolation. The sharper the curvature the smaller the unusable concentration span and the simpler the extrapolation. Theoretical calculations show clearly [*33*, *35*] and it is easily seen physically, that the larger the micelle the more cooperative is micelle formation and the sharper the curvature. Polydispersity of micelles can only smear out the transition region. Hence, pure systems show much better defined and more easily measured CMC's because of reduced polydispersity. For space-filling reasons, long-chain monomers can form larger spherical micelles, and do form larger micelles in general according to available experimental evidence [*8*]. Short-chain compounds, therefore, present an additional difficulty because of the spread of their CMC region not only in absolute terms but also in relative ones.

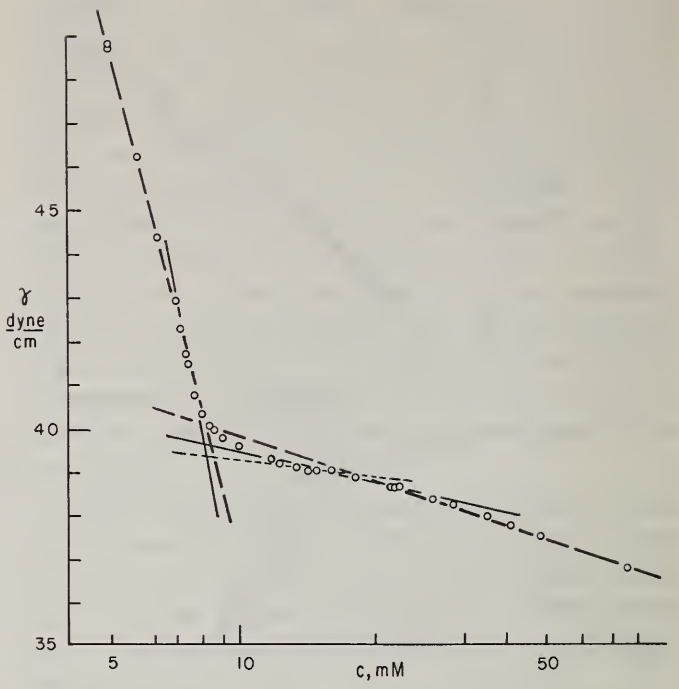

FIGURE 6. *The effect of the range of values used upon the CMC.*
Surface tension data for highly purified sodium dodecyl sulfate from reference 66007. The various straight lines represent extrapolation based on points within a certain range of concentrations. If points outside this range were not available, each of these extrapolations could be considered as quite reasonable.

The combined effects of curvature at higher concentrations and of the relative width of the transition region account for the fact that we have not been able to include any C–8 compounds among those for which confirmed or recommended values are available. This is despite the fact that these compounds are intrinsically easier to prepare in a state of high purity, that the measurement of the physical properties of their solutions can be made

more precisely and that any impurities in the solvent are less disturbing just because the CMC's are higher.

Long-chain compounds present different but no less serious difficulties because their CMC's are so low. Here the actual measurement of the physical property becomes difficult because it often differs little from that of the solvent, the control of concentration may become a problem because surfactants tend to adsorb at interfaces, and trace impurities in the solvent play a larger role. Furthermore, the compounds themselves are intrinsically less easily purified because certain operations, such as distillation of intermediates, become more difficult, and also because there is an increased number of isomers and because properties of homologues and isomers become more similar. In our collection only one value for a C–16 compound became recommended and an inordinate fraction is marked "D" for disputed, reflecting the difficulties involved.

Thus, the bulk of reliable CMC data deals with compounds in the C–10 to C–14 range. It is clear that better experimental methods are needed to extend the upper limit and better interpretation to overcome the lower one.

5. *The effect of indicators.* A very large fraction of all reported CMC values was obtained by methods involving the deliberate addition of an indicator, generally a dye which is solubilized and presents an easily measurable difference in the solubilized and not-solubilized state. This requires a discussion of the role of these indicators and of the reasons which led us to accept certain of these methods as valid and to reject the great majority as likely to be biased by significant methodical errors.

Solubilization is the marked increase of solubility associated with the formation of micelles. It is of special interest for substances which are sparingly soluble in water but is not limited to these. To a first approximation the excess solubility is directly proportional to the concentration of micelles [36] showing that these act as a solvent having a limited solvent power for the solubilizate. We can consider the saturated solution as an equilibrium system in which both the true solvent (water) and the micelles are saturated with the solubilizate. In undersaturated systems there are good reasons to believe [*36*, *37*] that a distribution equilibrium between water and micelles exists.

It is a well-known rule of physical chemistry that the activity of the solvent is lower in a solution than in the pure state. Hence, in the macroscopic world, the liquid phase forms at a lower vapor pressure in the presence of a solute than in its absence. In fact, at equilibrium the first drop always forms at the vapor pressure of the saturated solution. In the microscopic world of the micelle considered as a solvent, the analogy is clear: the activity of the surfactant in the micelle is lower in the presence of a solubilizate. Hence, micelles form at a lower concentration of monomers in the presence of the solubilizate. In fact, the first micelles exist at the equilibrium monomer concentration corresponding to a micelle saturated with the solubilizate under the conditions of the experiment. Two conclusions can, therefore, be drawn: the presence of a solubilized indicator always lowers the CMC, and this lowering reaches a maximum if the micelle is saturated with the indicator during the determination.

If the solubilizate is assumed to form an ideal solution in the micelle and related simplifying assumptions are made, it has been shown by Shinoda [*38*] that the CMC is changed by a factor $(1-1.36x)$ for an ionic surfactant where x is the mole fraction of additive in the micelle. For the nonionic case, the factor becomes simply $(1-x)$. The value of x depends, of course, on the concentration of micelles at the point taken as the CMC, the total available amount of indicator, and its solubility in water and in the micelle.

An additional and often neglected complication occurs when the indicator is a high molecular weight organic ion such as most of the dyes used in the spectral change methods, in particular pinacyanole. If the charge of the dye is the opposite of that of the surfactant, an insoluble salt may form. In fact, such a salt generally does form [*39–41*] as is evident from the color change produced by sub-CMC amounts of surfactant. This precipitate often remains finely dispersed by an excess of the surfactant and escapes detection. It is this precipitate which then becomes solubilized by micelles when the concentration of surfactant is further increased, causing a second color change that is generally reported as the CMC. The indicators are mostly used in small concentrations $(10^{-4}-10^{-5}M)$ so that the amount of surfactant consumed by precipitation is often negligible compared to the CMC but can become significant for low CMC's.

The presence of this water-insoluble precipitate has, however, a more profound effect on the determination of the CMC: it maintains a saturated solution until the last of the precipitate is dissolved. This also

corresponds to the end of at least one absorbancy change, the disappearance of the color of the precipitate (the γ band for pinacyanole) [*39*]. Hence, it has the effect of producing the maximum lowering of the CMC through the actual determination range in many of these methods. Lowering the dye concentration reduces the fraction of surfactant used up in precipitating the dye but does not affect significantly the degree of saturation of the micelles at the color change.

Saturation by the indicator in case of *oppositely* charged dyes is particularly objectionable because of their frequently high solubility in the micelles. Thus, the solubility of pinacyanole was estimated at 15 to 20 mole percent, in the first mixed micelles that formed [*39*].

There are other methods of CMC determinations in which the situation is more favorable, either because saturation of the micelle is avoided or because the mole fraction at saturation is much lower. In the former category falls the use of *similarly* charged dyes. The formation of a water-insoluble, micelle-soluble salt is then avoided; the dye remains in aqueous undersaturated solution and its mole fraction in the micelle is only a corresponding fraction of saturation. Unfortunately, no methodical studies on this approach are known to us. In the same class are dye or iodine methods used with nonionic surfactants.

Some of the solubilization methods use nonionic, water-insoluble dyes whose solubility in the micelles is known to be low. "Orange OT" is the most popular of these, and here it is known [*42–44*] that the mole fraction at saturation is about 0.01, thus producing a generally negligible error. Some of the other solubilized indicators such as lauryl alcohol or toluene are likely to lead to mole fractions, and hence CMC changes, of the order of 10 percent or more.

The above discussion makes clear our objection to accepting values, obtained in the presence of easily solubilized indicators under conditions favoring saturation, as valid CMC measurements for the surfactant itself. They are classified as G as far as "Method Quality" is concerned, indicating that a substantial methodical error is likely to be present. On the other hand, such data could be, in principle, excellent values for the mixed system (surfactant + indicator + water). In the great majority of the cases this is not so because the conditions are not sufficiently specified and the proportion of additive often unstated. In some cases, however, we were able to treat the data in just this way and some of the indicators may be found among the additives.

6. *The effect of impurities.* What has been said above about the effect of indicators applies to the effect of any impurities with the important provision that indicators are added consciously and generally specified in an article, whereas impurities are included inadvertently and their nature is uncertain. We have always scanned an article for clues to the presence and nature of impurities. Such clues can be found in details of the method of preparation, of analyses, and of other physical constants or properties reported. The results are included in our "quality rating" of the compound. In general we have been more skeptical of the older measurements performed before concern about the effect of impurities became widespread and modern analytical techniques were developed. We have given great weight to foam purification at a concentration below the CMC and to chromatographic methods.

The effect of impurities upon the CMC value depends both on the nature of the impurities and on the method used in the determination. We can learn something about the effects of different classes of impurities from their effects upon the CMC when they are added deliberately as "additives." Some have little effect unless present in concentrations too high ever to be reached by impurities. Hydrophilic organic compounds such as sugar or ethanol are in this class as are "inert" salts. On the other hand, oleophilic impurities and salts containing ions forming water-insoluble easily solubilized precipitates can have large effects as we have seen in connection with indicators because they tend to saturate the few micelles present at the CMC and lower the activity of surfactant in them. Higher homologues or incompletely reacted organic intermediates such as alcohols are among objectionable impurities likely to be encountered.

The case of true soaps, i.e., salts of higher carboxylic acids, merits a special mention. Here the acid itself, highly water-insoluble and easily solubilized, is the most important impurity. Some of it is normally formed by hydrolysis and must be considered as a normal constituent of the (water-surfactant) system. Additional substantial amounts are readily formed unless the presence of atmospheric carbon dioxide is carefully excluded. If precautions to this effect were not explicitly mentioned, we assumed that the system was impure and gave it a "D" rating. The effect of CO_2 can be largely neutralized by operating in the presence of a slight

excess of base. The CMC is not likely to differ substantially from that of the pure system but we have always reported such experiments among systems with additives, specifying the nature and concentration of the base used whenever possible.

The effect of an impurity upon different methods of determining the CMC is largely unknown. Some of our unpublished experiments suggest that traces have a larger effect on values obtained by plotting the equivalent conductivity than those obtained by plotting the specific conductance for the same systems. Dye indicator methods seem to give particularly low results in the presence of higher homologues or intermediates because both tend to concentrate in the first mixed micelles formed. It is likely that pinacyanole may change color by dissolving in droplets of emulsified higher alcohol far below the CMC [*45*].

The best studied effect is that of a surface active impurity upon the surface tension method. It is now well understood that such impurities may lower the surface tension significantly below the CMC and then become solubilized sufficiently in micelles to be more or less completely removed from the surface [*6, 46–48*]. This leads then to a higher surface tension after an intermediate minimum. As already mentioned, such minima have been often used as CMC values but we now take them as *prima facie* evidence of the presence of easily solubilized—and therefore significant—impurities or hydrolysis products.

An impurity leading to a minimum must have a surface activity at least comparable with that of the surfactant. If the surfactant is very surface active, the same impurity may remain unnoticed. This is shown by experiments of Harrold [*49*] who found that addition of salt (which increases the surface activity of the ionic surfactant much more than that of the alcohol) leads to a disappearance of the minimum along with a lowering of surface tension and of the CMC. Hence, the more surface active the surfactant, the less significant is the absence of a minimum as a criterion of purity.

When a minimum is present it becomes difficult if not impossible to obtain an accurate value for the CMC from surface tension measurements. However, even when a minimum is absent it seems that the surface tension method is particularly strongly affected by traces of impurities. This is a point which became apparent gradually in the course of our evaluations. Initially, we rated careful surface tension measurements showing no minima as BB. Later,

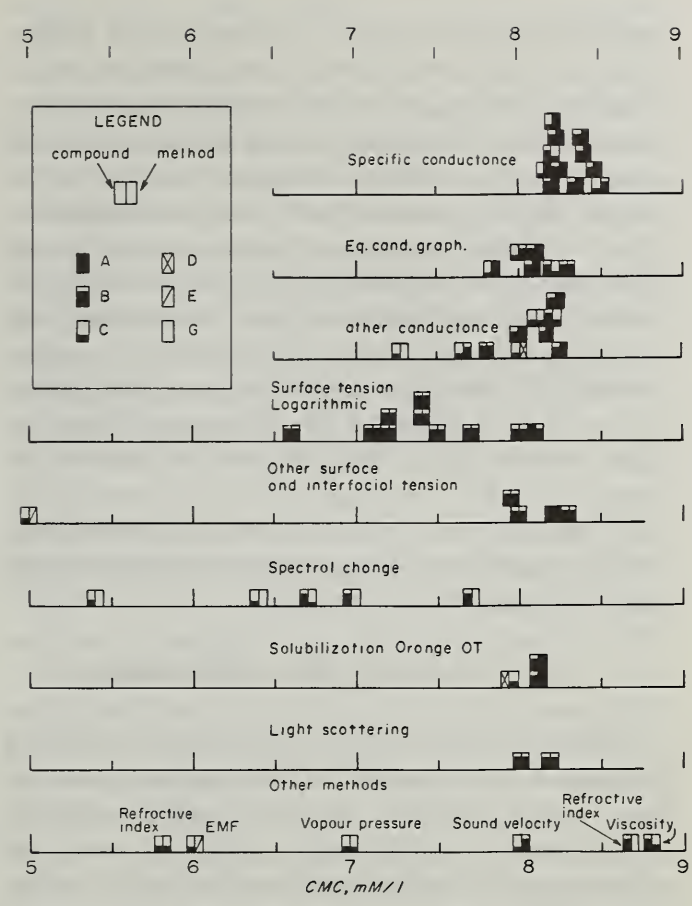

FIGURE 7. *All the critical micelle concentrations for sodium dodecyl sulfate at temperatures between 20 and 30 °C, carrying a quality rating of C–G or better, obtained by various experimental methods.*

Each square represents a determination and as shown in detail in the legend. the amount of black increases with the quality of the determination. It may be seen that CMC's determined by surface tension from a logarithmic plot scatter much more than other high-quality data obtained by a single method.

we found that this was often an overestimate of the accuracy of the method, although the details of the source of error remain obscure. Figure 7 illustrates our case. It shows all the measurements rated CC or better, and CG for sodium dodecyl sulfate at $25 \pm 5°$. Values obtained by different methods are shown on separate lines and the shading of the points indicates their individual quality rating. It may be seen that for conductance methods and for the miscellaneous ones the better values cluster together and the methodical difference mentioned earlier between equivalent and specific conductance plots is visible. The spectral change methods give, as would be expected, widely scattered results. However, the surface tension values rated BB, although not nearly as bad as the spectral change ones, cover a surprisingly wide range and show no clustering near the CMC expected for the pure compound. Part of this may be due to differences in extrapolation, but measurements on an especially

carefully purified sample (foamed in situ) yielded much more acceptable values using different ranges of points. This suggests that residual impurities are to blame. It also suggests that for surfactants having greater surface activity the effect may well be reduced, but there are no data to test this hypothesis.

As a result of these considerations we did not depend on surface tension values alone for any "confirmed" result although we have used them occasionally to confirm results obtained by another method. We have also used them more liberally for the nonionic compounds both because these are more surface active and because alternatives are fewer.

For the sake of consistency, we have maintained the BB rating for this type of data throughout in the individual quality evaluations.

7. Scope of this Collection

Micelle-forming systems cover a wide variety of molecular species which have in common one feature often described as amphipathy, a built-in asymmetry in the molecule which is composed of a nonpolar, hydrophobic portion, and a polar, hydrophilic part. The systems we have covered include monomers containing straight or branched aliphatic chains, sometimes partly or completely halogenated, and sometimes partly aromatic, with a wide variety of head groups, nonionic, zwitterionic, or ionic, including a variety of counterions in the last case. The solvents are aqueous, partially or completely; in a few systems the medium is heavy water. The variables which are explicitly cataloged, are temperature, pressure (except when it is atmospheric), the nature and the concentration of additives to the medium, the experimental method used, and the type and source of the CMC data themselves.

Certain types of systems were excluded intentionally. The reasons for such exclusions are given.

The association of monomers to produce oligomers and multimers in solution is a frequently observed phenomenon. The existence of a critical micelle concentration, however, requires fairly large multimers (containing roughly 20 or more monomers) in preference to small oligomers. Thus, for example, if monomers associate to produce dimers. trimers, and higher multimers with approximately equal stepwise association constants (the association constant describing the equilibrium between the Nth mer, the $(N+1)$th mer and the monomer), the degree of aggregation is a mild function of the total concentration; the aggregates are very polydisperse, and the system does not show any pronounced critical concentration.

The difference between systems which exhibit fairly sharp critical concentrations and those which do not is obviously a matter of degree. It seems, however, that the requirement of relatively greater stability of large multimers as compared to small oligomers is met mainly by monomeric systems which contain some flexible aliphatic chains. Those monomers which contain fused aromatic ring systems, such as dyes and other flat organic molecules, or fused alicyclic systems such as bile-salts, are expected to have, and seem to have in fact, rather diffuse and extended concentration ranges over which the degree of association increases from low to high values. For many such systems, CMC values have been reported in the literature [*50*]. Because of the relatively greater uncertainty of defining and determining the CMC values in such systems, particularly when the average degree of association is small, we have not extended our compilation to such systems. We have, however, recorded CMC values for many systems where the monomer is partly aromatic and partly aliphatic.

The phenomenon of micelle formation in aqueous systems is primarily a result of hydrophobic interactions. Hydrophobic interactions are a net result of a number of factors involving structural rearrangements of water molecules and solute-solvent, solvent-solvent, and solute-solute van der Waal's interactions. It is, therefore, not unlikely that in solvents other than water, similar interactions, perhaps on a reduced scale, can occur to produce other kinds of "solvophobic" bonding. In our compilation, we have many examples of mixed aqueous-nonaqueous systems including such media as 96 percent sulfuric acid. It is expected that future research will provide examples of micellization in many other completely nonaqueous systems where the micelles will have essentially the same kind of structure as in aqueous media, namely a hydrocarbonoid core and a polar interface.

When the medium is nonpolar, however, e.g., benzene or other hydrocarbon-like solvents, it is relatively improbable that the hydrophobic moiety of the monomers will have any great tendency to aggregate. For such systems, any aggregation that occurs is more likely to be due to the association of the hydrophilic groups of the monomers, which are now "solvophobic," to produce micelles of the

opposite kind of structure, i.e., "invert micelles," having a core composed of the hydrophilic groups of the monomers with the hydrocarbon groups remaining outside. Although such associations have been studied, and CMC values have been quoted [*51–54*], considerable uncertainty remains about their significance. We have, therefore, excluded such systems from our compilation.

Well above the CMC, in aqueous media, there occur extensive interactions between micelles, which are often difficult to unravel, particularly if the micelles are ionic. In such concentrated solutions, many physical properties of solutions exhibit breaks or kinks somewhat similar to the ones that occur at the CMC where micelles first form. The concentrations where such breaks or kinks occur are often described as "the second CMC" [*55, 56*]. The second CMC is not well understood, but it clearly involves changes in inter-micellar interactions as also monomer-micelle interactions. These "higher CMC" values have also been excluded from our compilation.

While the above restrictions imposed on our compilation are voluntary, there are some involuntary omissions and probable errors which must be mentioned. Of foremost concern, of course, is that many publications must have been missed altogether. A balance has had to be struck between completeness of coverage (up to December 1966) and inordinate delays in producing this report. It is hoped that not many high quality data on well-characterized systems have been omitted. It is probably unwise to hazard a guess as to what percentage of available CMC values in the literature has been missed, but we hope that it is below 10 percent. It is possible, also, that some CMC values in the publications we have examined have been unintentionally overlooked. We hope that readers of this report who note either of such omissions will draw them to our attention.

8. Methods and Techniques in the Collection of Data

This section deals with some of the problems we encountered in the retrieval of the literature pertaining to CMC measurements and in obtaining numerical values of the CMC.

Because of the wide-spread importance of and interest in surfactants in solution, CMC values appear in a wide variety of journals. As the values themselves are often of auxilliary and secondary interest to the main purposes of the investigation, neither the expression "critical micelle concentration" nor the word "micelle" may appear in the title of the articles. For the standard methods of literature search using Chemical Abstracts and other such publications, we, therefore, had to use a variety of key words for searching purposes. Use was made whenever possible of published books and review articles for the entries they provide into the literature. It was found necessary, however, to make extensive use of personal appeals to various investigators in the field of surfactant solutions to provide references to published work.

To obtain numerical values of the CMC, several procedures had to be used, as indicated by the source symbols. All numerical values quoted in the publications were given the source symbol T. The majority of these values were found in tables, but a substantial number were found dispersed in the written part of the text of the papers. It was necessary, therefore, to scrutinize the whole paper carefully. Of about 4700 numerical values reported in this compilation, 3207, or 68 percent, were obtained from this "direct" source. Numerical data were thus not available in the published literature for about 1500 CMC values which had to be obtained from various "indirect" sources described below.

In many publications, CMC values themselves are presented in graphical form, or some measured physical property of surfactant solutions is plotted as some function of the concentration, so that the CMC can be obtained from the "breaks" in the curves. A large number of numerical values of this type, i.e., values which are not given in the papers, were obtained by indirect means. A total of 598 values, given the source symbol L, involve, in addition to the published data, a private communication from an author. 515 values were "read" from published graphs and are given the source symbol G. 122 values used combined sources, GL. 90 CMC values were obtained from the kinks of published graphs of some physical property vs. concentration and are given the source symbol K.

In many publications, numerical values of some physical property measured, e.g., conductance, are tabulated as a function of concentration. When such measurements seemed to be of high quality, we obtained CMC values by making plots ourselves of the physical property measured. These CMC values, 96 in all, were given the source symbol P.

A small number of values, 21, were obtained by solving published equations relating numerical

values of some physical property, particularly conductance, with concentration, below and above the CMC. These have the source symbol E.

43 CMC values have combined source symbols, e.g., TL, KL, indicating dual sources of the values. These include 13 containing the symbol A, which denotes values which have been corrected for obvious misprints.

A substantial number of entries in the compilation do not report numerical CMC values because the entries either give a cross-reference to mixed surfactant systems, involve references to published graphical data for which retrieval was uncertain, or relate to numerical values obtained using criteria which we consider questionable.

The private correspondence from several investigators contained numerical data and references to unpublished work. We have not used these data in our present compilation.

A partial justification of the use of the various "indirect" sources referred to above is that their contributions to the categories of all selected data are high. Out of 620 data included in the categories 1, 2, 3, and D, only 270 were obtained from tabulated sources, T. Thus, 56 percent of all selected data are from "indirect" sources. Similarly, of the 106 confirmed (1) and recommended (2) CMC values, 67 are from "indirect" sources, not readily available from the literature.

588 DODECYL DIMETHYLAMMONIOPROPANE SULFONATE

PART 3. *Grouped by structure of hydrophobic part and arranged by number of carbon atoms in longest hydrophobic tail and by charge*—Continued

591 DODECYL DIMETHYLPHOSPHONIOPROPANE SULFONATE
595 DODECYL DIMETHYL AMMONIOPROPANE SULFATE
594 DODECYL DIPROPYL AMMONIOPROPANE SULFONATE
593 DIMETHYL DODECYLAMMONIOPROPANE HYDROXY SULFONATE
20 DODECYL BETA D GLUCOSIDE
649 ALPHA-D-GLUCOSYL DODECANE
205 DODECYL /OXYETHYLENE/12 OXYMETHYL REDUCED POLYDISPERSION OF HEAD GROUPS
325 DODECYL/OXYETHYLENE/4 ALCOHOL REDUCED POLYDISPERSITY OF HEAD GROUPS
377 DODECYL/OXYETHYLENE/ 5 ALCOHOL HOMOGENEOUS HEAD GROUP
110 DODECYL /OXYETHYLENE/ 6 ALCOHOL HOMOGENOUS HEAD GROUP
468 DODECYL/OXYETHYLENE/6.2 ALCOHOL NATURAL DISTRIBUTION OF HEAD GROUPS
115 DODECYL /OXYETHYLENE/7 ALCOHOL REDUCED POLYDISPERSION OF HEAD GROUPS
488 DODECYL/OXYETHYLENE/7 ALCOHOL HOMOGENEOUS HEAD GROUP
469 DODECYL/OXYETHYLENE/7.6 ALCOHOL NATURAL DISTRIBUTION OF HEAD GROUPS
163 DODECYL /OXYETHYLENE/ 8 ALCOHOL NATURAL DISTRIBUTION OF HEAD GROUPS
489 DODECYL/OXYETHYLENE/9 ALCOHOL HOMOGENEOUS HEAD GROUP
310 DODECYL/OXYETHYLENE/10 ALCOHOL NATURAL DISTRIBUTION OF HEAD GROUPS
470 DODECYL/OXYETHYLENE/10.6 ALCOHOL NATURAL DISTRIBUTION OF HEAD GROUPS
490 DODECYL/OXYETHYLENE/12 ALCOHOL HOMOGENEOUS HEAD GROUP
164 DODECYL /OXYETHYLENE/ 12 ALCOHOL NATURAL DISTRIBUTION OF HEAD GROUPS
326 DODECYL/OXYETHYLENE/14 ALCOHOL REDUCED POLYDISPERSITY OF HEAD GROUPS
471 DODECYL/OXYETHYLENE/15.8 ALCOHOL NATURAL DISTRIBUTION OF HEAD GROUPS
716 DODECYL /OXYETHYLENE/16 ALCOHOL REDUCED POLYDISPERSITY OF HEAD GROUPS
165 DODECYL /OXYETHYLENE/ 18 ALCOHOL NATURAL DISTRIBUTION OF HEAD GROUPS
472 DODECYL/OXYETHYLENE/20.4 ALCOHOL NATURAL DISTRIBUTION OF HEAD GROUPS
327 DODECYL/OXYETHYLENE/23 ALCOHOL REDUCED POLYDISPERSITY OF HEAD GROUPS
166 DODECYL /OXYETHYLENE/ 23 ALCOHOL NATURAL DISTRIBUTION OF HEAD GROUPS
473 DODECYL/OXYETHYLENE/27.1 ALCOHOL NATURAL DISTRIBUTION OF HEAD GROUPS
170 DODECYL /OXYETHYLENE/ 28 ALCOHOL REDUCED DISTRIBUTION OF HEAD GROUPS
116 DODECYL /OXYETHYLENE/30 ALCOHOL REDUCED POLYDISPERSION OF HEAD GROUPS
474 DODECYL/OXYETHYLENE/38.6 ALCOHOL NATURAL DISTRIBUTION OF HEAD GROUPS
475 DODECYL/OXYETHYLENE/67.3 ALCOHOL NATURAL DISTRIBUTION OF HEAD GROUPS

Abbreviations: Units of Measure

Code	Description
A	MOLES/100 MOLES OF SOLVENT (INCLUDING ADDITIVES)
B	VOLUME % OF SOLVENT
C	MOLES/100 MOLES OF SURFACTANT MIXTURE
D	W/V % (GRAMS/100 MILLILITERS OF SOLUTION)
E	% SATURATION OF SOLUTION BY ADDITIVE
H	GRAMS/100 GRAMS OF SOLVENT
I	MOLES/100 MOLES OF SURFACTANT
K	TOTAL NORMALITY OF COUNTERIONS
M	MOLAR (MOLES/LITER OF SOLUTION)
N	NORMAL (EQUIVALENTS/LITER OF SOLUTION)
P	W/W % (GRAMS/100 GRAMS OF SOLUTION)
Q	GRAMS/100 GRAMS OF SURFACTANT
R	VALUE VARIED DURING EXPERIMENT
S	MOLES/KILOGRAM OF SOLUTION
T	GRAMS/100 GRAMS OF SURFACTANT MIXTURE
U	MOLES/LITER OR KILOGRAM OF SOLUTION (UNSPECIFIED)
W	MOLAL (MOLES/KILOGRAM OF SOLVENT)
Y	PRESSURE IN ATMOSPHERES

Abbreviations: Words and Names

Abbreviations	Meaning	Abbreviations	Meaning
AZBZ	AZOBENZENE	N-3SOA*	N-(3SULFOLANYL) OLEYL AMIDE
BRPB	BROMPHENOL BLUE (DYE)	OROT	ORANGE OT (DYE)
BZL*	BENZYL	PDMAB	P-DIMETHYLAMINOAZOBENZENE
BZP4	BENZOPURPURINE 4B (DYE)	PLT	PLOT (GRAPH)
COND	CONDUCTANCE (ELECTRIC)	PMS*	POLYMETHYLSILOXANE
DCFL	DICHLOROFLUORESCEINE (DYE)	PNCN	PINACYANOL
DMYL	DIMETHYL YELLOW (DYE)	RHD6	RHODAMINE 6G (DYE)
EOSN	EOSINE (DYE)	SDN4	SUDAN 4 (DYE)
EQN	EQUATIONS	SKYB	SKY BLUE SF (DYE)
ERTS	ERYTHROSIN (DYE)	SP	SPECIFIC
FL	FLUORESCEINE (DYE)	SPCTR	SPECTRAL
FLUOR	FLUORESCENCE	TMCHCGLET*	TRIMETHYL CYCLOHEXYL CARBINYL GLYCEROL ETHER
FOTMTR	PHOTOMETRIC		
GLET*	GLYCERINE ETHER	TNSN	TENSION
HXMTP*	HEXAMETAPHOSPHATE	UNSPEC	NOT SPECIFIED BY REFERENCE
INPX	INDOPHENOL (DYE)	V.BR*	VERY BRANCHED
I2	IODINE	YLOB	YELLOW OB (DYE)
LOGMIC	LOGARITHMIC GRAPH	2NPA	2-NITRODIPHENYLAMINE
LOH	LAURYL (DODECYL) ALCOHOL		

Source Symbols

Source Code	Description
A	MISPRINT CORRECTED IN FIGURE QUOTED IN REFERENCE
C	UNITS CONVERTED FROM TABULATION IN REFERENCE
E	FROM EQUATIONS IN REFERENCE OF METHOD RESULTS
G	FROM GRAPH OF CMC VALUES IN REFERENCE
K	FROM GRAPH OF METHOD RESULTS IN REFERENCE
L	ALSO PERSONAL COMMUNICATIONS FROM AUTHOR
M	UNITS CONVERTED FROM PRECEDING
P	FROM OUR PLOT OF DATA IN REFERENCE
S	AVERAGE OF TABULATED VALUES
T	TABULATED OR FIGURE QUOTED IN REFERENCE

The code E in the numerical value of the concentration in the "Additive" column of the CMC tables stands for "times ten to the power".

Symbols for the quality of materials and methods are discussed on page 6 et seq.

Symbols for methods are discussed on page 8 et seq.

Announcement of New Publications in
National Standard Reference Data Series

Superintendent of Documents,
Government Printing Office,
Washington, D.C. 20402

Dear Sir:

Please add my name to the announcement list of new publications to be issued in the series: National Standard Reference Data Series—National Bureau of Standards:

Name_____

Company_____

Address_____

City_____ State_____ Zip Code_____

(Notification key N–337)

Publications in the National Standard Reference Data Series
National Bureau of Standards

You may use this listing as your order form by checking the proper box of the publication(s) you desire or by providing the full identification of the publication you wish to purchase. The full letter symbols with each publications number and full title of the publication and author must be given in your order, e.g. NSRDS–NBS–17, Tables of Molecular Vibrational Frequencies, Part 3, by T. Shimanouchi.

Pay for publications by check, money order, or Superintendent of Documents coupons or deposit account. Make checks and money orders payable to Superintendent of Documents. Foreign remittances should be made either by international money order or draft on an American bank. Postage stamps are not acceptable.

No charge is made for postage to destinations in the United States and possessions, Canada, Mexico, and certain Central and South American countries. To other countries, payments for documents must cover postage. Therefore, one-fourth of the price of the publication should be added for postage.

Send your order together with remittance to Superintendent of Documents, Government Printing Office, Washington, D.C. 20402.

- ☐ NSRDS-NBS 1, **National Standard Reference Data System—Plan of Operation,** by E. L. Brady and M. B. Wallenstein, 1964 (15 cents).
- ☐ NSRDS-NBS 2, **Thermal Properties of Aqueous Uni-univalent Electrolytes,** by V. B. Parker, 1965 (45 cents).
- ☐ NSRDS-NBS 3, Sec. 1, **Selected Tables of Atomic Spectra, Atomic Energy Levels and Multiplet Tables, Si II, Si III, Si IV,** by C. E. Moore, 1965 (35 cents).
- ☐ NSRDS-NBS 3, Sec. 2, **Selected Tables of Atomic Spectra, Atomic Energy Levels and Multiplet Tables, Si I,** by C. E. Moore, 1967 (20 cents).
- ☐ NSRDS-NBS 3, Sec. 3, **Selected Tables of Atomic Spectra, Atomic Energy Levels and Multiplet Tables, C I, C II, C III, C IV, C V, C VI,** by C. E. Moore, 1970 (in press).
- ☐ NSRDS-NBS 4, **Atomic Transition Probabilities, Volume 1, Hydrogen Through Neon,** by W. L. Wiese, M. W. Smith and B. M. Glennon, 1966 ($2.50).
- ☐ NSRDS-NBS 5, **The Band Spectrum of Carbon Monoxide,** by P. H. Krupenie, 1966 (70 cents).
- ☐ NSRDS-NBS 6, **Tables of Molecular Vibrational Frequencies, Part 1,** by T. Shimanouchi, 1967 (40 cents).
- ☐ NSRDS-NBS 7, **High Temperature Properties and Decomposition of Inorganic Salts, Part 1, Sulfates,** by K. H. Stern and E. L. Weise, 1966 (35 cents).
- ☐ NSRDS-NBS 8, **Thermal Conductivity of Selected Materials,** by R. W. Powell, C. Y. Ho, and P. E. Liley, 1966 ($1.00).
- ☐ NSRDS-NBS 9, **Bimolecular Gas Phase Reactions (rate coefficients),** by A. F. Trotman-Dickenson and G. S. Milne, 1967 ($2).
- ☐ NSRDS-NBS 10, **Selected Values of Electric Dipole Moments for Molecules in the Gas Phase,** by R. D. Nelson, Jr., D. R. Lide, Jr., and A. A. Maryott, 1967 (40 cents).
- ☐ NSRDS-NBS 11, **Tables of Molecular Vibrational Frequencies, Part 2,** by T. Shimanouchi, 1967 (30 cents).
- ☐ NSRDS-NBS 12, **Tables for the Rigid Asymmetric Roto: Transformation Coefficients from Symmetric to Asymmetric Bases and Expectation Values of P_z^2, P_z^4, and P_z^6,** by R. H. Schwendeman, 1968 (60 cents).
- ☐ NSRDS-NBS 13, **Hydrogenation of Ethylene on Metallic Catalysts,** by J. Horiuti and K. Miyahara, 1968 ($1.00).
- ☐ NSRDS-NBS 14, **X-Ray Wavelengths and X-Ray Atomic Energy Levels,** by J. A. Bearden, 1967 (40 cents).
- ☐ NSRDS-NBS 15, **Molten Salts, Vol. 1, Electrical Conductance, Density, and Viscosity Data,** by G. Janz, F. W. Dampier, G. R. Lakshminarayanan, P. K. Lorenz, and R. P. T. Tomkins, 1968 ($3).
- ☐ NSRDS-NBS 16, **Thermal Conductivity of Selected Materials, Part 2,** by C. Y. Ho, R. W. Powell, and P. E. Liley, 1968 ($2).
- ☐ NSRDS-NBS 17, **Tables of Molecular Vibration Frequencies, Part 3,** by T. Shimanouchi, 1968 (30 cents).
- ☐ NSRDS-NBS 18, **Critical Analysis of the Heat-Capacity Data of the Literature and Evaluation of Thermodynamic Properties of Copper, Silver, and Gold From 0 to 300 K,** by G. T. Furukawa, W. G. Saba, and M. L. Reilly, 1968 (40 cents).
- ☐ NSRDS-NBS 19, **Thermodynamic Properties of Ammonia as an Ideal Gas,** by L. Haar, 1968 (20 cents).
- ☐ NSRDS-NBS 20, **Gas Phase Reaction Kinetics of Neutral Oxygen Species,** by H. S. Johnson, 1968 (45 cents).
- ☐ NSRDS-NBS 21, **Kinetic Data on Gas Phase Unimolecular Reactions,** by S. W. Benson and H. E. O'Neal ($7).
- ☐ NSRDS-NBS 22, **Atomic Transition Probabilities, Vol. II, Sodium Through Calcium, A Critical Data Compilation,** by W. L. Wiese, M. W. Smith, and B. M. Miles ($4.50).
- ☐ NSRDS-NBS 23, **Partial Grotrian Diagrams of Astrophysical Interest,** by C. E. Moore and P. W. Merrill, 1968 (55 cents).
- ☐ NSRDS-NBS 24, **Theoretical Mean Activity Coefficients of Strong Electrolytes in Aqueous Solutions from 0 to 100° C,** by Walter J. Hamer, 1968 ($4.25).
- ☐ NSRDS-NBS 25, **Electron Impact Excitation of Atoms,** by B. L. Moiseiwitsch and S. J. Smith, 1968 ($2).
- ☐ NSRDS-NBS 26, **Ionization Potentials, Appearance Potentials, and Heats of Formation of Positive Ions,** by J. L. Franklin, J. G. Dillard, H. M. Rosenstock, J. T. Herron, K. Draxl, and F. H. Field ($4).
- ☐ NSRDS-NBS 27, **Thermodynamic Properties of Argon from the Triple Point to 300 K at Pressures to 1000 Atmospheres,** by A. L. Gosman, R. D. McCarty, and J. G. Hust ($1.25).
- ☐ NSRDS-NBS 28, **Molten Salts, Vol. 2, Section 1, Electrochemistry of Molten Salts: Gibbs Free Energies and Excess Free Energies From Equilibrium-Type Cells,** by G. J. Janz and C. G. M. Dijkhuis. **Section 2, Surface Tension Data,** by G. J. Janz, G. R. Lakshminarayanan, R. P. T. Tomkins, and J. Wong ($2.75).
- ☐ NSRDS-NBS 29, **Photon Cross Sections, Attenuation Coefficients and Energy Absorption Coefficients and Energy Absorption Coefficients From 10 keV to 100 GeV,** by J. H. Hubbell (75 cents).
- ☐ NSRDS-NBS 30, **High Temperature Properties and Decomposition of Inorganic Salts, Part 2, Carbonates,** by K. H. Stern and E. L. Weise (45 cents).
- ☐ NSRDS-NBS 31, **Bond Dissociation Energies in Simple Molecules,** by B. deB. Darwent (55 cents).
- ☐ NSRDS-NBS 32, **Phase Behavior in Binary and Multicomponent Systems at Elevated Pressures: *n* Pentane and Methane *n* Pentane,** by V. M. Berry, 1970 (70 cents).
- ☐ NSRDS-NBS 33, **Electrolytic and Conductance and the Conductances of the Acids in Water,** by W. J. Hamer and H. J. DeWane, 1970 (50 cents).
- ☐ NSRDS-NBS 34, **Ionization Potentials and Ionization Limits Derived from the Analyses of Optical Spectra,** by C. E. Moore, 1970 (75 cents).

Latest developments in the subject area of this publication, as well as in other areas where the National Bureau of Standards is active, are reported in the NBS Technical News Bulletin. See following page.

HOW TO KEEP ABREAST OF NBS ACTIVITIES

Your purchase of this publication indicates an interest in the research, development, technology, or service activities of the National Bureau of Standards.

The best source of current awareness in your specific area, as well as in other NBS programs of possible interest, is the TECHNICAL NEWS BULLETIN, a monthly magazine designed for engineers, chemists, physicists, research and product development managers, librarians, and company executives.

If you do not now receive the TECHNICAL NEWS BULLETIN and would like to subscribe, and/or to review some recent issues, please fill out and return the form below.
